This conception of the information society, while it draws on sociology and economics, has at its core the geographer’s distinctive stress on space. Here, the major

emphasis is on the information networks that connect locations and, in consequence, have dramatic effects on the organization of time and space. It has become an increasingly popular index of the information society, largely because of a remarkable trilogy written by Manuel Castells titled *The Information Age (1996–1998)* in which he describes a “network society.”^[40,41]

Goddard^[42,43] identifies several interrelated elements in the transition to an information society. These include:

- Information is coming to occupy center stage as the “key strategic resource” on which the organization of a world economy is dependent.

The modern world demands the coordination of globally distributed manufacture, planning across and between sovereign states, and marketing throughout continents. What might be called the globalization of enterprise—from production, through distribution, to marketing—means that economic (and other) affairs are increasingly conducted on a world scale. As historian Eric Hobsbawm has observed, especially from the 1960s, a world economy began to come into existence “which actually has no specifiable territorial base or limits,” and by the early 1970s, such a transnational economy became an effective global force. The inexorable logic of this for the participants, chiefly transnational corporations that are “the dominant forces in the world economy,”^[44] is to develop global strategies and mechanisms to maximize their comparative advantages. Information, or what Peter Dicken calls the “circulation activities” that “connect the various parts of the production system together,”^[44] is axial to these diverse activities, thus of heightened importance in the contemporary world. It follows too that “information management” is of exceptional pertinence and that, as a result, we witness the rapid expansion of information occupations.

- Computer and communications technologies provide the infrastructure that enables information to be processed and distributed. These technologies allow information to be handled on an historically unprecedented scale, to facilitate instantaneous and real-time trading, and to monitor economic, social, and political affairs on a global stage.
- There has been an exceptionally rapid growth of the “tradeable information sector” of the economy, by which Goddard means to highlight the explosive growth of services such as new media (satellite broadcasting, cable, video) and on-line databases providing information on a host of subjects ranging from stock market dealings, commodity prices, patent listings, currency fluctuations, to scientific and technological journal abstracts.

Complementing these developments has been the radical reorganization of the world’s financial system that has

resulted in the collapse of traditional boundaries that once separated banking, brokerage, financial services, credit agencies, and the like. Inside this bewildering world of high finance—which few people understand and still fewer appear able to control—circulates, in electronic form, dazzling sums of capital (one estimate suggests there are \$2 trillion Eurodollars in the system, though there were none just over a generation ago^[45]). It might be hard to conceptualize, but it is difficult to underestimate the import of the growth of an integrated global financial market. With sophisticated IT systems now in place, plus the deregulation of stock markets and the abolition of exchange controls, we now have facilities for the continuous and real-time flow of monetary information, for round-the-clock trading in stocks, bonds, and currencies. The scale and speed of these information flows is astonishing. Hutton,^[46] for instance, observes that foreign exchange turnover dwarfs the size of national economies and makes trade flows (a traditional method of measuring national economic activity in terms of import and export levels) appear small in comparison. Thus “the total level of world merchandise trade in 1993 is two-thirds of US Gross Domestic Production; it will take turnover in the foreign exchange markets less than a fortnight to reach the same total.”^[46]

Courtesy of immediate and effective information processing and exchange economics has become truly global and with this has come about a reduction in the constraints of space. Companies can now develop global strategies for production, storage, and distribution of goods and services; financial interests operate continuously, respond immediately, and traverse the globe. The boundaries erected by geographical location are being pushed further and further back—and with them too the limitations once imposed by time—thanks to the virtuoso ways in which information can be managed and manipulated in the contemporary period.

Such developments emphasize the centrality of information networks linking together locations within and between towns, regions, nations, continents and, indeed, the entire world. As the electricity grid runs throughout an entire nation, extending down to the individual household, so too we may envisage now a “wired society”^[47] operating at the national, international, and global level to provide an “information grid”^[48] to each home, shop, or office. Increasingly, we are all connected to the network—which itself is expanding its reach and capacities. We come across it personally at many levels: in electronic point of sale terminals in shops and restaurants, in accessing data across continents, in e-mailing colleagues, or in exchanging information on the Internet. We may not personally experience it, but the ‘information ring main’ functions still more frantically at the level of international banks, intergovernmental agencies, and corporate relationships.

In many writings, emphasis is put on the technological bases of the information network.^[49] Perhaps predictably

then with these accounts of an emerging network society considerable attention is given to advances in and obstacles to the development of an ISDN infrastructure.^[50] However, notwithstanding the importance of technology and actually providing a salutary reminder of the easily neglected centrality of telecommunications to IT developments, most thinkers concerned with the emergence of a “network marketplace” place stress on ways in which networks underline the significance of the flow of information.^[40]

The salient idea here is of information circulating along electronic “highways.” Interestingly, no one has been able to quantify how much and at what rate information must flow along these routes to constitute an information society. In fact, no one has produced reliable figures capable of giving us an overall understanding of information traffic.^[51] We have data on telephone density in relation to population, figures on the expansion of facsimile services, statistics for sales of computer systems, automated telecommunications exchanges, and so on, but lack a clear picture of the size, capacity, and use of the networks.

Nevertheless, all observers are aware of a massive increase in transborder data flows, in telecommunications facilities, in communications between computers at every level from home to transnational organization, in exchanges between stock markets and corporate segments, in access to international databases, in telex messages, and in uptake of the Internet. Similarly, there is considerable awareness of increases in the global distribution of mass mediated information: satellite television being the obvious and preeminent example, though one would also have to include news gathering and distribution services in any adequate picture. As Mulgan has it, “the networks carry an unimaginable volume of messages, conversations, images and commands”^[52]

Why much greater volume and velocity of information flows should impel us to think in terms of the constitution of a new type of society returns us to the geographer’s special concern with space. All things happen in particular places and at specific times, but the characteristics of space and time have been transformed with the advent of the network society. Where once trade was cumbersome and slow moving across distances, nowadays it can be effected instantaneously with computerized communications technologies; where once corporate activity had to be coordinated by slow-moving letter that took days and even weeks to cross the space that divided the interested parties, nowadays it takes place in real time courtesy of sophisticated telecommunications and video-conference facilities.

A world built on networks calls into question older conceptions of space and power. Where the early market economies grew out of the temporal and spatial regularities of city life, today’s are built on the logical or “virtual” regularities of electronic communications, a new geography of nodes and hubs, processing and control centers.

The nineteenth century's physical infrastructure of railways, canals, and roads are now overshadowed by the network of computers, cables, and radio links that govern where things go, how they are paid for, and who has access to what.^[52]

In short, the constraints of space have been dramatically limited, though certainly not eliminated. And, simultaneously, time has itself been "shrunk" as contact via computer communications and telecommunications is immediate. This "time/space compression," as Giddens^[53] terms it, provides corporations, governments, and even individuals with hitherto unachievable options.

No one could deny that information networks are an important feature of contemporary societies: Satellites do allow instantaneous communications round the globe; databases can be accessed from Oxford to Los Angeles, Tokyo, and Paris; facsimile machines and interconnected computer systems are a routine part of modern businesses.

Yet, we may still ask: Why should the presence of networks lead analysts to categorize societies as information economies? And, when we ask this, we encounter the problem of the imprecision of definitions once again. For instance, when is a network a network? Two people speaking to one another by telephone or computer systems transmitting vast data sets through a packet switching exchange? When an office block is "wired" or when terminals in the home can communicate with local banks and shops? The question of what actually constitutes a network is a serious one and it raises problems not only of how to distinguish between different levels of networking but also of how we stipulate a point at which we have entered a network/information society.

Finally, one could argue that information networks have been around for a very long time. From, at very least, the early days of the postal service, through to telegram and telephone facilities, much economic, social, and political life is unthinkable without the establishment of such information networks. Given this long-term dependency and incremental, if accelerated, development, why should it be that in the 1980s commentators began to talk in terms of information societies?

CULTURAL

The final conception of an information society is perhaps the most easily acknowledged, yet the least measured. Each of us is aware, from the pattern of our everyday lives, that there has been an extraordinary increase in the information in social circulation. There is simply a great deal more of it about than ever before.

Television has been in extensive use for well over 40 years in Britain, but now its programming is pretty well round-the-clock, people being able to watch from breakfast time until the early morning. It has expanded from a single channel and discontinuous service to include now

five broadcast channels, while digitalization of television, now well advanced, will bring a huge increase of channels within the next decade or so. This has been enhanced to incorporate video technologies, cable and satellite channels, and even computerized information services such as teletext. An avalanche of computerized games has become attached to Personal Computers and virtual reality products have begun to enter the home. There is very much more radio output available now than even a decade ago, at local, national, and international levels. And radios are no longer fixed in the front room, but spread through the home, in the car, in the office, and, with the walkman, everywhere. Movies have long been an important part of people's information environment and, indeed, attendances at cinemas have significantly declined. But movies are today very much more prevalent than ever: available still at cinema outlets, broadcast on television, readily borrowed from video rental shops, cheaply purchased from the shelves of chain stores. Walk along any street and it is almost impossible to miss the advertising displays, the billboards, and the window arrangements in shops. Visit any railway or bus station and one cannot but be struck by the widespread availability of paperback books and inexpensive magazines—their subject matter ranging from classical, pulp fiction, middlebrow, to self-therapy—a scale and scope without precedent. In addition, audiotape, compact disc and radio all offer more, and more readily available, music, poetry, drama, humor, and education to the general public. Newspapers are extensively available and a good many new titles fall on our doorsteps as free sheets. Junk mail is delivered daily.

All of this testifies to the fact that we inhabit a media-laden society, but the informational features of our world are more thoroughly penetrative than a short list of television, radio, and other media systems suggests. This sort of listing implies that new media surround us, presenting us with messages to which we may or may not respond. But, in truth, the informational environment is a great deal more intimate, more constitutive of us, than this suggests. One may consider, for example, the informational dimensions of the clothes we wear, the styling of our hair and faces, the very ways in which, nowadays, we work at our image (from body shape to speech, people are intensely aware of the messages they may be projecting and how they feel about themselves in certain clothes, with a particular hairstyle, etc.). A few moment's reflection on the complexities of fashion, the intricacy of the ways in which we design ourselves for everyday presentation, makes one well aware that social intercourse nowadays involves a greater degree of informational content than previously.

To be sure, there has long been adornment of the body, clothing, and makeup being important ways of signaling status, power, and affiliation. But, it is obvious that historically the present age has dramatically heightened the symbolic import of dress and the body. When one considers the lack of range of meaning that characterized the

peasant smock that was the apparel of the majority for centuries, and the uniformity of the clothing worn by the industrial working class in and out of work up to the 1950s, then the veritable explosion of meaning in terms of dress since then is remarkable. The availability of cheap and fashionable clothing, the possibilities of affording it, and the accessibility of any amount of groups with similar—and different—lifestyles and cultures (divided by age, gender, race, ethnicity, affluence, region, etc.) all make one appreciate the informational content even of our bodies.

Homes too are informational laden in an historically singular way. Furniture, layout, and decorative design all express ideas and ideals: the G-plan style, the Laura Ashley settee, the William Morris wallpaper and the mixing of some and all of these according to choice and budget. Certainly, since the days of the Industrial Revolution, homes have signified ways of life—one thinks, for example, of the style of the “respectable” working class of the late Victorian period or the distinctive design of the professional middle classes between the wars. But, it is the explosion in variety, and the accessibility of it to a great many, that is most remarkable. With this has come an astonishing vista of signification.

This intrusion of information into the most intimate realms of home, bedroom and body is complemented by the growth of institutions dedicated to investing everyday life with symbolic significance. One thinks of the global advertising business, of publishing empires, of the fashion industry, of worldwide agencies of media production that bring to the domestic scene reflections of our own ways of life and images of other lifestyles, thereby presenting us with alternative meanings that may be absorbed, rejected, and reinterpreted by people, but all the time adding to the vocabulary of the symbolic environment.

Contemporary culture is manifestly more heavily information laden than any of its predecessors. We exist in a media-saturated environment that means that life is quintessentially about symbolization, about exchanging and receiving—or trying to exchange and resisting reception—messages about ourselves and others. It is in acknowledgment of this explosion of signification that many writers conceive of our having entered an information society. They rarely attempt to gauge this development in quantitative terms but rather start from the “obviousness” of our living in a sea of signs, one fuller than at any earlier epoch.

It is not difficult to explain why this should be so. For most of history, people would have lived in relatively fixed conditions with neighbors who would have been well-known to one another since all lived in the same location. Today, life is characteristically one of the interaction of strangers, each with a heightened sense of their individuality and the choices open to them. Nowadays, people live for only a few years in one place before moving on; daily, they make decisions about what to wear,

buy, eat, and do from a range that to their forebears would have seemed astonishingly broad; during the day, they are likely to meet others about whom they know little; urban dwelling is the norm. In a world of strangers, it is essential that people have means of communication to reach out to others, to establish their own identities, and to exchange information. Obviously, the spoken word is central to this, and this vocabulary has expanded over the years, but so too are goods, cars, clothes, and so forth because they provide us with “languages” with which to connect to a changing world.

Into this—the familiar story of a shift from community to association that appears to be accelerating—needs to be placed the spectacular expansion of media technologies^[54] that help produce conditions in which much of life today is experienced symbolically rather than personally encountered: news is not passed from word of mouth by people who know one another, but electronically from around the globe; our work is very often concerned with exchanging symbols with others with whom we do not come into personal contact, but substitute for by writing or telephone communications; our entertainment is more often made by watching a screen than by personally attending a show.

Furthermore, it is easy to appreciate that this world of signification is also characterized by constant change and, accordingly, with persistent shifts and strains in the symbolic environment. Just think of the proliferation of lifestyles nowadays (among students, social classes, the young, family forms, etc.), or reflect on the rapidly changing appeal of intellectual ideas, of musical tastes, and of fashionable “looks,” and consider the innovation, conflicts, misunderstandings, and tumult that this engenders.

Paradoxically, it is perhaps this very explosion of information that leads some writers to announce, as it were, the death of the sign. Blitzed by signs all around us, designing ourselves with signs, unable to escape signs wherever we may go, the result is, oddly, a collapse of meaning. As Baudrillard puts it: “there is more and more information, and less and less meaning.”^[55] In this view, signs once had a reference (clothes, for example, signified a given status, the political statement a distinct philosophy, the television news, “what really happened”). However, in this, the post-modern era, we are enmeshed in such a bewildering web of signs that they lose their salience. Signs come from so many directions and are so diverse, fast-changing, and contradictory, that their power to signify is dimmed. In addition, audiences are creative, self-aware, and reflective, so much so that all signs are greeted with skepticism and a quizzical eye, hence, easily inverted, reinterpreted and refracted from their intended meaning. Thus, the notion that signs represent some “reality” apart from themselves loses its credibility. Rather signs are self-referential: they—simulations—are all there is. They are, again to use Baudrillard’s terminology, the “hyper-reality.”

People appreciate this situation readily enough: They deride the poseur who is dressing for effect, but

acknowledge that it's all artifice anyway; they are skeptical of the politician who "manages" the media and his image through adroit PR (Public Relations), but accept that the whole affair is a matter of information management and manipulation. Here, it is conceded that people do not hunger for any true signs, because they recognize that there are no longer any truths. In these terms, we have entered an age of "spectacle" in which people realize the artificiality of signs they may be sent ("it's only the president at his latest photo opportunity," "it's news manufacture," "it's Jack playing the tough guy") and in which they also acknowledge the inauthenticity of the signs they use to construct themselves ("I'll just put on my face," "there I was adopting the 'worried parent' role").

As a result, signs lose their meaning and people simply take what they like from those they encounter (usually very different meanings than may have been intended at the outset). And then, in putting together signs for their homes, work, and selves, happily revel in their artificiality, "playfully" mixing different images to present no distinct meaning, but instead to derive "pleasure" in the parody or pastiche of, say, combining punk and a 1950s Marilyn Monroe facial style. In this information society we have then "a set of meanings (that) is communicated (but which) have no meaning."^[56]

Experientially, this idea of an information society is easily enough recognized, but, as a definition of a new society, it is considerably more wayward than any of the notions we have considered. Given the absence of criteria we might use to measure the growth of signification, it is difficult to see how students of postmodernism such as Mark Poster can depict the present as one characterized by a novel "mode of information."^[56] How can we know this other than from our sense that there is more symbolic interplay going on? And on what basis can we distinguish this society from say, that of the 1920s, other than purely as a matter of degree of difference? Those who reflect on the postmodern condition may have interesting things to say about the character of contemporary culture, but, as regards establishing a clear definition of the information society, they are glaringly deficient.

QUALITY AND QUANTITY

Reviewing these varying definitions of the information society, what comes clear is that they are either or both underdeveloped or imprecise. Whether it is a technological, economic, occupational, spatial, or cultural conception, we are left with highly problematical notions of what constitutes, and how to distinguish, an information society.

It is important that we remain aware of these difficulties. Though as a heuristic device, the term information society might have some value in helping us to explore features of the contemporary world, it is far too inexact to

be acceptable as a definitive term. For this reason, though one may readily acknowledge that information plays a critical role in the present age, one has to remain suspicious as regards information society scenarios and maintain skepticism toward the view that information has become the chief distinguishing feature of our times.

Now, however, I want to raise some further difficulties with the language of the information society. The first problem concerns the quantitative versus qualitative measures to which I have already alluded. My earlier concern was chiefly that quantitative approaches failed to distinguish more strategically significant information activity from that which was routine and low-level and that this homogenization was misleading. Here I want to reraise the quality/quantity issue insofar as it bears upon the question of whether the information society marks a break with previous sorts of society.

Most definitions of the information society offer a quantitative measure (numbers of white collar workers, percentage of GNP devoted to information, etc.) and assume that, at some unspecified point, we enter an information society when this begins to predominate. But there are no clear grounds for designating as a new type of society one in which all we witness is greater quantities of information in circulation and storage. If there is just more information, then it is hard to understand why anyone should suggest that we have before us something radically new. This is a point made well by Giddens when he observes that all societies, as soon as they are formed into nation states, are information societies in so far as routine gathering, storage, and control of information about population and resources are essential to their operation.^[57] On this axis, all that differentiates the present era from, say seventeenth-century England, is much greater quantities of information that are amassed, dissembled, and processed. Kumar voices much the same complaint against postindustrial theorists (and postindustrial society is currently synonymous with the concept of an information society): How can they uphold the claim to have identified a postindustrial society when the trends they single out "are extrapolations, intensifications, and clarifications of tendencies which were apparent from the very birth of industrialism?"^[58]

Against this, however, it may be feasible to describe as a new sort of society, one in which it is possible to locate information of a qualitatively different order and function. Moreover, this does not even require that we discover that a majority of the workforce is engaged in information occupations or that the economy generates a specified sum from informational activity. For example, it is theoretically possible to imagine an information society where only a small minority of information experts hold decisive power. One need look only to the writings of H.G. Wells to conceive of a society in which a "knowledge elite" predominates and the majority, surplus to economic requirement, are condemned to drone-like unemployment.

On a quantitative measure, say of occupational patterns, this would not qualify for information society status, but we could feel impelled to so designate it because of the decisive role of information/knowledge to the power structure and direction of social change.

The blunt point is that quantitative measures—simply more information—cannot of themselves identify a break with previous systems, while it is at least theoretically possible to regard small but decisive qualitative changes as marking a system break. After all, just because there are many more automobiles today than 30 years ago does not qualify us to speak of a “car society.” But, it is a systemic change that those who write about an information society wish to spotlight, whether it be in the form of Bell’s postindustrialism, or in Castells’s informational mode of development, or in Poster’s mode of information.

What is especially odd is that so many of those who identify an information society as a new type of society do so by presuming that this qualitative change can be defined simply by calculating how much information is in circulation, how many people work in information jobs, and so on. What we have here is the assumption that quantitative increases transform—in unspecified ways—into qualitative changes in the social system.

It is noticeable that those scholars such as Schiller and Harvey who stress the present’s continuities with the past, while they acknowledge an increasingly central role played by information, have at the forefront of their minds the need to differentiate between categories of information and the purposes to which it is put. In other words, those who insist that the “informationalized” society is not radically different from the past are at pains to differentiate information on qualitative grounds. For instance, they will examine how information availability has been affected by the application of market criteria and contend that the wealthier sectors of society gain access to particularly high quality information that consolidates their privileges and powers. Yet, while they emphasize these sort of qualitative dimensions of informatization, they do so to highlight continuities of the socioeconomic system. Conversely, those who consider that the information society is a radically different system most often recourse to quantitative indices to demonstrate a profound qualitative change.

Roszak^[59] provides an interesting insight into this paradox in his critique of information society themes. His examination emphasizes the importance of qualitatively distinguishing “information,” extending to it what each of us does on an everyday basis when we differentiate between phenomena such as data, knowledge, experience, and wisdom. Certainly, these are themselves slippery terms, but they are an essential part of our daily lives. In Roszak’s view, the present “cult of information” functions to destroy these sort of qualitative distinctions that are the stuff of real life. It does this by insisting that information is a purely quantitative thing subject to statistical

measurement. But to achieve calculations of the economic value of the information industries, of the proportion of GNP expended on information activities, of the percentage of national income going to the information professions, and so on, the qualitative dimensions of the subject (Is the information useful? Is it true or false?) are laid aside: “For the information theorist, it does not matter whether we are transmitting a fact, a judgement, a shallow cliché, a deep teaching, a sublime truth, or a nasty obscenity.” These qualitative issues are overlooked as information is homogenized and made amenable to numbering: “Information comes to be a purely quantitative measure of communicative exchanges.”^[59]

The astonishing thing to Roszak is that along with this quantitative measure of information comes the assertion that more information is profoundly transforming social life. Having produced awesome statistics on information activity by blurring the sort of qualitative distinctions we all make in our daily lives, information society theorists then assert that these trends are set to change qualitatively our entire lives. To Roszak, this is the mythology of “information” talk: The term disguises differences, but in putting all information into one big pot, instead of admitting that what we get is an insipid soup, the perverse suggestion is that we have an elixir. As Roszak says, this may be very useful for those who wish the public to accept unprotestingly change since it seems so uncontentious.

Information smacks of safe neutrality; it is the simple, helpful heaping up of unassailable facts. In that innocent guise, it is the perfect starting point for a technocratic political agenda that wants as little exposure for its objectives as possible. After all, what can anyone say against information?^[59]

Roszak vigorously contests these ways of thinking about information. A result of a diet of statistic upon statistic about the uptake of computers, the data-processing capacities of new technologies, and the creation of digitalized networks, is that people come readily to believe that information is the essential sustenance of the social system. There is so much of this food that it is tempting to agree with those information society theorists who insist that we have entered an entirely new sort of system. But against this “more-quantity-of-information-to-new-quality-of-society” argument Roszak insists that the “master ideas” that underpin our civilization are not based upon information at all.^[60] Principles such as all men are created equal, my country right or wrong, live and let live, we are all God’s children, and do unto others as you would be done by are central ideas of our society—but all come before information.

It is important to say that Roszak is not arguing that these and other master ideas are necessarily correct (in fact a good many are noxious—e.g., all Jews are rich, all women are submissive, blacks have natural athletic ability). But, what he is emphasizing is that ideas, and the necessarily qualitative engagement these entail, take

precedence over quantitative approaches to information. And, what he especially objects to is that information society theorists reverse that situation at the same time as they smuggle in the (false) idea that more information is fundamentally transforming the society in which we live.

WHAT IS INFORMATION?

Roszak's rejection of statistical measures leads us to consider perhaps the most significant feature of approaches to the information society. We are led here largely because his advocacy is to reintroduce qualitative judgment into discussions of information. Roszak asks questions like: Is more information necessarily making us a better informed citizenry? Does the availability of more information make us better informed? What sort of information is being generated and stored and what value is this to the wider society? What sort of information occupations are expanding, why, and to what ends?

What is being proposed here is that we insist on examination of the meaning of information. And, this is surely a commonsensical understanding of the term. After all, the first definition of information that springs to mind is the semantic one: Information is meaningful; it has a subject; it is intelligence or instruction about something or someone. If one were to apply this concept of information to an attempt at defining an information society, it would follow that we would be discussing these characteristics of the information. We would be saying that information about these sorts of issues, those areas, that process, are what constitutes the new age. However, it is precisely this commonsensical definition of information that the information society theorists jettison. What is, in fact, abandoned is a notion of information having a semantic content.

The definitions of the information society I have reviewed perceive information in nonmeaningful ways. That is, searching for quantitative evidence of the growth of information, a wide range of thinkers have conceived it in the classic terms of Shannon and Weaver's^[61] information theory. Here, a distinctive definition is used, one that is sharply distinguished from the semantic concept in common parlance. In this theory, information is a quantity that is measured in "bits" and defined in terms of the probabilities of occurrence of symbols. It is a definition derived from and useful to the communications engineer whose interest is with the storage and transmission of symbols, the minimum index of which is on/off (yes/no or 0/1). This approach allows the otherwise vexatious concept of information to be mathematically tractable, but this is at the price of excluding the equally vexing—yet crucial—issue of meaning and, integral to meaning, the question of the information's quality. On an everyday level, when we receive or exchange information, the prime concerns are its meaning and value: Is it significant, accurate,

absurd, interesting, adequate, or helpful? But, in terms of the information theory that underpins so many measures of the explosion of information, these dimensions are irrelevant. Here, information is defined independent of its content, seen as a physical element as much as is energy or matter. As one of the foremost information society devotees puts it:

Information exists. It does not need to be perceived to exist. It does not need to be understood to exist. It requires no intelligence to interpret it. It does not have to have meaning to exist. It exists.^[62]

In fact, in these terms, two messages, one that is heavily loaded with meaning and the other that is pure nonsense, can be equivalent. As Roszak says, here "information has come to denote whatever can be coded for transmission through a channel that connects a source with a receiver, regardless of semantic content."^[59] This allows us to quantify information but at the cost of abandonment of its meaning and quality.

If this definition of information is the one that pertains in technological and spatial approaches to the information society (where the quantities stored, processed, and transmitted are indicative of the sort of indexes produced), we come across a similar elision of meaning from economists' definitions. Here it may not be in terms of bits, but at the same time, the semantic qualities are evacuated and replaced by the common denominator of price.^[63]

To the information engineer, the prime concern is with the number of yes/no symbols, to the information economist, it is with their vendibility. But, as the economist moves from consideration of the concept of information to its measurement, what is lost is the heterogeneity that springs from its manifold meanings. The "endeavour to put dollar tags on such things as education, research, and art"^[64] unavoidably abandons the semantic qualities of information. Kenneth Boulding observed thirty years ago that "The bit abstracts completely from the content of information and while it is enormously useful for telephone engineers for purposes of the social system theorist we need a measure which takes account of significance and which would weight, for instance, the gossip of a teenager rather low and the communications over the hot line between Moscow and Washington rather high."^[65,66] How odd then that economists have responded to the qualitative problem that is the essence of information with a quantitative approach that, reliant on cost and price, is at best "a kind of qualitative guesswork,"^[64,65] "Valuing the invaluable," to adopt Machlup's terminology, means substituting information content with the measuring rod of money. We are then able to produce impressive statistics, but in the process we have lost the notion that information is about something.^[67]

Finally, though culture is quintessentially about meanings, about how and why people live as they do, it is striking that with the celebration of the nonreferential character of symbols by enthusiasts of postmodernism,

we have a congruence with communications theory and the economic approach to information. Here, too, we have a fascination with the profusion of information, an expansion so prodigious that it has lost its hold semantically. Symbols are now everywhere and generated all of the time, so much so that their meanings have imploded, hence ceasing to signify.

What is most noteworthy is that information society theorists, having jettisoned meaning from their concept of information in order to produce quantitative measures of its growth, then conclude that such is its increased economic worth, the scale of its generation, or simply the amount of symbols swirling around, that society must encounter profoundly meaningful change. We have, in other words, the assessment of information in nonsocial terms—it just is—but we must adjust to its social consequences. This is a familiar situation to sociologists who often come across assertions that phenomena are aloof from society in their development (notably technology and science) but that carry within them momentous social consequences. It is demonstrably inadequate as an analysis of social change.^[68]

Doubtless being able to quantify the spread of information in general terms has some uses, but it is certainly not sufficient to convince us that, in consequence of an expansion, society has profoundly changed. For any genuine appreciation of what an information society is like, and how different—or similar—it is to other social systems, we must surely examine the meaning and quality of the information. What sort of information has increased? Who has generated what kind of information, for what purposes, and with what consequences?

THEORETICAL KNOWLEDGE

It is tempting to stop this critique here, satisfied to have drawn attention to the peculiarly deracinated notion of information that plays a pivotal role in conceptions of the information society. However, there is another suggestion, intriguing if imprecise, that can contend that we are on the point of entry into a distinctly novel information society without any need to reflect on the meanings of the information involved. Furthermore, this proposition has it that we need not discover any of the quantitative measures of information expansion (information employees, tradeable information, etc.), because the suggestion is that it is a decisively qualitative change in information that can be pointed to and which marks a break with the past.

From this point of view, an information society is regarded as one in which theoretical knowledge takes on a preeminence that it has hitherto lacked. The theme that unites what is in fact rather a disparate range of thinkers is that, in this information society (though frequently the term knowledge society is preferred, for the obvious reason that it conjures much more than agglomerated bits of

information), affairs are organized and arranged in such a way as to prioritize theory.

It is worth noting that Bell^[30] presents this as an “axial principle” of postindustrial society and that, although the weight of his analysis leans toward quantitative increases in service—i.e., information—occupations as indicators of postindustrialism, he is emphatic that “what is radically new today is the codification of theoretical knowledge and its centrality for innovation.”^[69] It is easy enough to understand what Bell means by this when we contrast today’s postindustrialism with its predecessor industrial society.^[70] In the past, it is argued, innovations were made, on the whole, by “inspired and talented tinkerers who were indifferent to science and the fundamental laws underlying their investigations.” In contrast to this decidedly practical and problem-solving orientation, it is suggested by Bell that nowadays innovations start from theoretical premises. That is, now that we have arrived at a situation in which it is possible to codify known scientific principles, then our knowledge of these becomes the starting point of action. In this way, what was once dismissed as useless—as just theory—has become the axis of practical innovations.

Again, it is not difficult to find illustrations of this “change in the character of knowledge itself.”^[30] For instance, Alan Turing’s paper, “On Computable Numbers” (1937), sets out mathematical principles that underpin later applications in computer science; the development of integrated circuits that enabled the “microelectronics revolution” to get under way in the late 1970s was founded on known principles of solid-state physics; and innovations in areas as diverse as compact disc technology and nuclear energy were reliant on theoretical breakthroughs that were regarded initially as without practical consequences. It is rather difficult to think of technological applications nowadays that do not hinge on theoretical knowledge, whether it is calculating the needs of households for water supply, building a bridge, or estimating energy needs in a particular area. Not surprisingly, perhaps, we find historian Eric Hobsbawm confirming Bell’s perception, concluding that during this century, “the theorists (have been) in the driving seat. . . telling the practitioners what they were to look for and should find in the light of their theories.”^[71]

Bell takes his argument for the “primacy of theoretical knowledge” considerably further, to suggest that it is pre-eminent not only in the realm of technological innovation, but even in social and political affairs. For instance, governments today introduce policies based on theoretical models of the economy. These may be variable—Keynesian, monetarist, supply side, and so forth—but each of them are theories that are the foundations that underpin day-to-day decisions ministers may make in response to practical exigencies. Again, we can see emerging major concerns with environmental consequences of policies. The response is, arguably, not just to respond to a

particularly pressing problem (say, an oil spillage), but to act, increasingly, on the basis of theoretical models of the ecosystem's sustainability. To be sure, such models are at present inchoate and unrefined, but they and other instances help us to appreciate that, while theoretical knowledge does not have to be true in any absolute sense, it does play a decisive part in life in the late twentieth century.

Theoretical knowledge is undeniably an arresting idea, one that does, *prima facie* define a new type of society that hinges on the generation and use of information/knowledge. If theory is at the point of initiation of developments, in contrast to one-time practical demands, then such knowledge could be said to herald a new sort of society. Moreover, we are not talking here merely of more white-collar workers or more bits of information being produced but of a new foundational principle of social life.

Nonetheless, a major difficulty with this notion is defining with any precision what is meant by theoretical knowledge. Theory evokes abstract and generalizable rules, laws, and procedures, and, with this, there can be agreement that advances, especially in scientific knowledge, have resulted in their codification in texts that are learned by would-be practitioners and that, in turn, become integrated into their practical work. This principle can reasonably be thought to be at the heart of research and development projects at the forefront of innovations, but it is clearly in evidence, too, in a large range of professions such as architecture, building, handling of food, and even the design of much clothing.

However, there are those who would extend the notion of theoretical knowledge to encompass a much vaster range, all of which could be cited as evidence of a knowledge-based society. Here, for example, one might include the training of many white-collar employees in law, social services, accountancy, etc., as evidence of the primacy of knowledge in the contemporary world. Indeed, one might also choose to argue that the whole of higher education, at the least, is concerned with transmitting theoretical knowledge. After all, it is a common refrain that the rapid transition to mass higher education (with about 30% of the age group attending universities) has been required by the need to equip appropriately very large numbers of people to operate successfully in the knowledge society.^[72] Such knowledge as is transmitted is undoubtedly codified and generally abstracted from practical applications, and it is even generalizable, though it is surely of a different order of magnitude to the theoretical knowledge expounded in sciences such as chemistry and physics.

Stehr,^[73] proposing that we now inhabit a knowledge society, does extend the definition of theory in such a way, arguing that nowadays knowledge has come to be constitutive of the way that we live. Recourse to theoretical knowledge is now central to virtually everything that we do, from designing new technologies, producing everyday artifacts,^[74] to making sense of our own lives when we

draw upon large repositories of knowledge to help us better understand our own location. Here, we are surely extending the idea of theoretical knowledge a very great deal, but it is helpful in so far as Stehr does echo themes in the stimulating and original work of social theorist Anthony Giddens that merit some comment. Stehr^[73] proposes a three-fold typology of the development of knowledge, meaningful (the Enlightenment ideal of knowledge for better understanding), productive (knowledge applied to industry), to action (where knowledge is intimately connected to production with, for example, the inclusion of intelligent devices, and where it influences the performance of one's everyday activities). This latter form of knowledge appears close to Giddens's emphasis on what he refers to as the intensified reflexivity of "late modern" existence. What Giddens highlights here is that, and increasingly, modernity has been a story of people's release from the strictures of nature and restrictive forms of community where it appeared that one had to do what one did as it was a matter of fate, toward individuals and groups making choices about their own and collective destinies in circumstances of "manufactured uncertainty." That is, the world increasingly is not bounded by fixed and unchangeable limits, but is rather recognized as malleable and the outcome of human decisions. A requisite of this is heightened self and collective interrogation, otherwise reflexivity, though this is not to be perceived as some trend toward self-absorption. Quite the contrary, it is premised on openness to ideas, information, and theories from very diverse realms, which are examined and incorporated as circumstances and people so decide.

A key point here is that a posttraditional^[75,76] society that is characterized by intensified reflexivity of actors and institutions hinges on information/knowledge. Of course, some of this is local and particular (one's biography reflected upon, a company carefully scrutinizing its customer records), but a great deal is also abstract, emanating especially from electronic media and from other, notably educational, institutions. If one accepts Giddens's argument that we do inhabit a world of "high modernity" in which reflexivity is much more pronounced than hitherto, then it is feasible to conceive of this as heightening the import of information and knowledge in contemporary life. A world of choices, for both organizations and individuals, is reliant on the availability and generation of detailed and rich information. If one follows Giddens's contention that ours is an era of intensified reflexivity on the basis of which we forge our material, as well as psychological conditions, then it follows that this will sustain and will demand a complex and deep information environment. It is perhaps not quite the same sort of theoretical knowledge as that which Bell has proposed, but, in so far as it is frequently abstract and codified, then it could find inclusion in a suitably widened category.

Nevertheless, there are reasons why we should hesitate to depict any novel information society in these terms.

Not least is that Giddens himself is reluctant to do so. While he does emphasize that a “world of intensified reflexivity is a world of clever people,”^[76] he is unwilling to present this as other than an extension of long-term trends, hence as a high modern era rather than a postmodern or postindustrial epoch. Life today is certainly more information intensive, but this is not sufficient to justify projections that it represents an entirely new sort of society.

In addition, Giddens has also raised serious doubts about the novelty of theoretical knowledge. Several years ago, he observed that “there is nothing which is specifically new in the application of ‘theoretical knowledge’ . . . Indeed. . . rationality of technique. . . is the primary factor which from the beginning has distinguished industrialism from all preceding forms of social order.”^[77] This being so, we return to the problem of designating as novel today’s society in which theoretical knowledge is prevalent. Further, Giddens’s objection begs the key question: Just what, precisely, do commentators mean by theoretical knowledge? It is clear, from the quotation above, that Giddens feels that the classical sociologist Max Weber’s conception of formal rationality that underpins purposive action (most famously manifested in the growth of bureaucratic structures) might apply in one definition. After all, it involves abstract and codifiable principles, rules, and regulations (the entire bureaucratic machine), as well as requiring, from participants, command of abstract knowledge (how the system works). Theoretical knowledge, in these terms, is not much more than learning the rules and procedures of how bureaucracies function. If so, then one is forced also to ask what is especially new about this.

This leads us to the wider complaint about the imprecision of the term theoretical knowledge. If, for instance, the primacy of theoretical knowledge is taken to refer to known scientific principles (the boiling point of water, the conductivity of elements, etc.) that are codified in texts, then this is one matter. However, if theoretical knowledge is taken to include hypothetical models such as the relation between inflation and unemployment or social class and educational opportunity, then this surely is quite another. Again, if theoretical knowledge is conceived as the primacy of research and development funds and teams in modern innovations, then this is another matter too. And if theoretical knowledge is perceived as the prominence in modern life of expert systems that operate services like the water and sewerage systems, airlines, and retail organizations, then this is another thing again. Alternatively, if theoretical knowledge is to be understood as a trend toward very much more intensified reflexivity among individuals and institutions, on the basis of which they then shape their future courses of action, then this is another thing again. Finally, if the rise of theoretical knowledge is to be chartered by the spread of educational certification—a common strategy—then this is to introduce still another significantly different definition.

In view of such ambiguities of definition, at best, one can conclude that theoretical knowledge may be more in evidence than hitherto, but that it is a far cry from this to conclude either that it is the preeminent force in society or that it marks a decisive turning point in history.

CONCLUSION

This entry has focused on the criteria used by those who depict an information society. Each has been found wanting, chiefly because they forward inappropriate quantitative measures that cannot, in themselves, identify a qualitative change from one type of society to another. It was further demonstrated that conceptions of the information society operated with variable—but uniformly nonsemantic—definitions of information, whether it was conceived as so many bits, or so much economic worth, or as an explosion of signs. Such notions of information, all of which ignore its meaning/content, were useful in that they facilitate quantification, but they are unacceptable when it comes to suggesting that we are witnessing the emergence of a qualitatively new information society. Finally, the distinctively qualitative notion, that the primacy of theoretical knowledge is the distinguishing feature of the information/knowledge society was considered. While it has an initial appeal, the term was too vague and imprecise to persuade that the undoubted expansion of some forms of theoretical knowledge signal a new type of society.

Information Systems

E. Burton Swanson

Anderson School of Management, University of California, Los Angeles, Los Angeles, California, U.S.A.

Abstract

An information system provides information to help guide organizational actions. It typically features substantial human-computer interaction. Application software and a data base form the digital content around which a system is built. Among the different types are transaction-processing systems, management information systems, decision support systems, group support systems, and enterprise systems.

INTRODUCTION

An information system is commonly a computer-based system for providing information to an organization to help guide its actions.^[1] The term “information system” is also sometimes used in information science to refer to information retrieval systems based more on documents than on data, an application domain familiar to libraries, in particular. The term is sometimes also used very generally and informally, without reference to either computers or organizations. People sometimes refer to their own personal information systems, for instance. In this entry, we take the organizational perspective, which has its origins in business, but applies to organizations of every kind, including libraries.

In an organization, an information system typically features people working interactively with computers to accomplish a particular task. Human-computer interaction (HCI) enables both people and their machine extensions to be informed via the system. Where decisions are routine and highly structured, they may sometimes be automated and relegated to the machine.^[2] Often, the information provided serves to coordinate workers’ specialized but necessarily collective efforts. The varieties of information systems are many, reflecting the diversity of organizations and tasks to be accomplished. A typical large business firm has information systems to support its accounting and finance, operations, supply chain management, sales and marketing, customer service, human resource management, and research and development. But information systems are found everywhere, in organizations of all kinds and sizes, public as well as private.

This entry discusses information systems both as a subject and as a field of study and practice. In the sections to follow, information systems are first described in terms of their: (1) origins; (2) varieties; and (3) practices. As information systems also constitute: (4) an evolving field of study and practice with; (5) attendant social issues, these aspects too are considered.

ORIGINS

Modern information systems emerged with the rise and spread of digital computing in the 1950s, although punched card tabulating equipment was in use for data processing in organizations before then. The stored-program computer itself was initially viewed as a high-powered calculating device, suitable primarily for numerical and other sophisticated analyses. Such “scientific computing” was distinguished from what was termed “electronic data processing” (EDP), which emerged about the same time to support the more prosaic work of business, such as accounting.^[3] In the 1960s, computers came to be designed and marketed specifically for business purposes, eventually displacing the tabulating equipment. Notably, a high-level programming language for business applications, Common Business-Oriented Language (COBOL), was also developed, which emphasized data and file structures, and deemphasized the computational features found in FORMula TRANslation (FORTRAN), the language most commonly used in scientific computing. COBOL ultimately became the most widely used programming language for the development of application software for information systems on mainframe computers. As much of this code remains in use, the language persists even today.

Beyond business-oriented application software, the emergence of data base technology in the late 1960s was central to the rapid rise and spread of large-scale information systems among firms. A data base is an organized collection of related data files.^[4] A data base management system (DBMS) is system software that enables data bases to be managed as integrated wholes, where relationships among files are clearly delineated. With a DBMS, data can be defined via a data dictionary and managed separately from the different software which access it. Finally, the articulation of the relational data model as a foundation for data bases spurred the development of relational data bases in the 1970s, which came to dominate the field.^[5] Today, Oracle provides the leading relational data base

software for medium to large firms, while Microsoft's Access is well established among small businesses.

Together, application software and a related data base have come to form the digital content around which any modern information system is now built. Typically, the application software incorporates the "business rules" to be followed, while the data base incorporates the "business facts" that shape the data processing, for instance, in processing a business payroll, or in selling seats to a concert, or in managing the circulation of a library's holdings, or in almost any other endeavor in which carefully informed organizational actions are routinely taken. While the business facts and data base will typically be specific to the enterprise, the business rules and application software may be either specific or generic, i.e., commonly used, as with accounting systems that incorporate professionally mandated rules and principles. Where the business rules and application software is specific to the organization, it may underpin the unique capabilities of the enterprise, in which case it may be strategic.^[6] Today, people in a wide variety of occupations and in organizations large and small are likely to work interactively with information systems to accomplish much of their work. Through networks and the Web and Internet, in particular, and through the use of laptops and mobile devices they engage in this HCI from wherever they happen to be and at whatever times they choose or are called upon to be available.

VARIETIES

Information systems come in a wide variety, reflecting the diversity in the organizations that employ them. Among business firms, some information systems will be characteristic of the industry, in particular, as with process control systems in chemical and refining enterprises, or electronic funds transfer (EFT) systems in banks and other financial services firms. However, certain basic types are found in enterprises of all kinds, reflecting both their historical origins based in then-new technologies and the nature of organization itself. These include transaction-processing systems; management information systems (MIS); decision support systems (DSS); group support systems; and enterprise systems. These are not pure types; actual systems may combine features of two or more basic types.

Transaction-Processing Systems

Transaction-processing systems support an enterprise in its transactions with others, such as customers, suppliers, and employees.^[7] Every business transaction involves an exchange of goods, services, money, and information in some combination between the parties. Transaction-processing systems exist to ensure the integrity of these

transactions. In today's world, each time a consumer makes a purchase with a credit card, withdraws cash from an account, or books an airline ticket, the consumer likely engages the other party's transaction-processing systems. Increasingly, a consumer does this directly, by swiping a bank card at a point-of-sale (POS) device or employing an automated teller machine (ATM) or initiating a purchase from the Web.

Beyond their primary function, transaction-processing systems also enable a business to coordinate its internal operations among units, especially in the making of goods, where parts are withdrawn from inventory and a manufactured item is assembled in a series of operations, and the final product eventually distributed from one location to another, for instance. Here and elsewhere, transaction-processing systems are basically event-driven, and are often engaged to authorize formal actions, such as accepting a customer order or authorizing a credit purchase. The business rules for such data processing may be quite sophisticated, as in credit authorization which incorporates rules aimed at fraud detection, for instance. The data pertaining to these events will ultimately serve to update a data base that is typically drawn upon in processing and is relied upon to give the current status of the organization's affairs. Where the data base is immediately updated as events happen, the system is said to operate in "real time." In the case of firms, basic transaction data will further feed the accounting systems that provide a formal financial picture of the ongoing business.

Where firms do business with each other, for instance, within a supply chain, their transaction-processing systems are also sometimes tied together by means of an interorganizational system that enables them to communicate directly with each other.^[8] For such machine-to-machine communication, this necessitates resolution of disparities in how the data themselves are defined by the communicating parties. The interorganizational system may be based on electronic data interchange (EDI) arrangements or increasingly on eXtensible Markup Language (XML) standards for exchange over the Web. The concept of Web services envisions a world of business services and firm transactions seamlessly tied together via standards for business data of all kinds.^[9]

Management Information Systems

Management information systems support an organization's hierarchical structure and are targeted to management at all levels. MIS aim to support every manager's need to know within his or her scope of responsibility, typically by extracting important performance information from data gathered from the organization's transaction-processing and operational systems and presenting it efficiently in tabular or graphical form. The concept of an MIS emerged in the 1960s and signaled an important transition in information systems, from traditional EDP to

systems that served more sophisticated purposes.^[10] In the United States, both practitioners and educators embraced the MIS concept and many business schools originated programs of study under this banner. Today the term continues to be widely used, although the more generic term “information systems” has become more common.

Executive information systems (EIS) were founded in the 1980s as a new form of MIS aimed at top management.^[11] The early EIS featured access to news external to the business, in addition to traditional performance metrics, and further employed new graphics and communications technologies. Most recently, executive support systems have been developed which provide a personalized Web page and “executive dashboard” of up-to-the-minute information with which the manager is to engage and steer the enterprise. These systems are now also popularly referred to as “business intelligence systems,” reflecting the sophisticated analytics that may lie behind the dashboard metrics.^[12]

Decision Support Systems

Decision support systems emerged in the 1970s as interactive systems that supported managers and other “knowledge workers” in tasks that were semi-structured, where decisions could be aided by analytical computer-based means.^[13] These systems shifted the original MIS focus from information to decisions. Early DSS featured innovative HCI employing graphics, formal models, and heuristics or algorithms as means of support. A pioneering example was IBM’s Geodata Analysis and Display Systems (GADS), which supported organizational decisions related to urban geography, such as arranging police beats and assigning school district boundaries.^[14] Today, the concept of geographical information systems (GIS) continues in this tradition as a major area of application supported by new technologies such as remote sensing, geographical positioning, graphical analytics, and visualization. The firm ESRI is the leading provider of GIS software.

The concept of group decision support systems (GDSS) extended the basic DSS concept in the 1980s. Substantial research led to the development of decision rooms equipped with systems that facilitated complex, interactive group decision making in a particular location.^[15] The early focus was typically on largely unstructured problems, with tools provided to support collective brainstorming and idea evaluation, for instance, while further capturing a record of the group meeting. With advances in communications technologies, the GDSS concept soon evolved into one that supported group work more broadly, where group members could be at multiple locations and could also meet asynchronously as needed.

Group Support Systems

Beyond the informational and decisional needs of managers, it is well understood that communication and

cooperation more broadly in the organization is required to coordinate the work undertaken within and across units. Certain of this communication and cooperation can be built into the work systems themselves; however, other organizational means such as cross-functional teams can also facilitate lateral communication, cooperation, and coordination, thus moderating the burden on the management hierarchy.^[16] Not surprisingly, given the ubiquity of group work in organizations, a wide variety of systems have in recent years been originated to support group work, in particular.

The concept of computer-supported collaborative work (CSCW) originated in the 1980s to characterize designs for computer-enabled group work, understood to require substantial communication and coordination, typically over time and across locations.^[17] Lotus Notes exemplified the software then deployed in these new systems and remains in wide use today. Current groupware in support of group work is diverse and includes, e.g., that which provides for electronic meetings, electronic mail and messaging, calendar management, project and document management, knowledge sharing, workflow management, and collaborative design. Today, group work can also be organized and conducted on the Web, making use of a commercially available service.

Enterprise Systems

Enterprise systems emerged in the 1990s with the rise of enterprise resource planning (ERP), a concept for integrating the major functional systems of the enterprise, in particular, the organization’s financial, human resource, and operational systems around a common data base.^[18] The principal means of integration was typically a software package provided by a vendor such as SAP or Oracle. Firms sought to replace their older and disparate home-grown legacy systems, which required high maintenance, with standard off-the-shelf software that promised an integrated solution to relieve them of this burden. ERP basically incorporated the firm’s major transaction-processing and operational systems. Its adoption was further given a large boost by concerns related to the millennium bug and the threat it posed at the time to vulnerable legacy systems. Today, most large firms have adopted and implemented ERP in the form of packaged software provided by one or more leading suppliers.

A second type of enterprise system termed customer relationship management (CRM) has more recently also become popular, focusing on the “front office” of a firm, beyond the already heavily computerized “back office.”^[19] A central CRM aim is to provide the firm with a “unified view” of its customers, who might otherwise engage in separate transactions with different business units, each in the absence of full customer information. Just as it promises better customer service, CRM also typically supports a firm’s sales force and enables it to be

better managed. Still another CRM aim is to help the firm assess the profitability of its different customer segments, in the interest of focusing marketing and customer retention initiatives on achieving higher overall profits.

PRACTICE

Information systems practice rests on four closely intertwined bodies of professional knowledge: (1) application knowledge; (2) technology knowledge; (3) development knowledge; and (4) management knowledge. Each is associated with job specialties in the field.

Application Knowledge

Application knowledge refers to the domain in which the information system supports work within the organization. The system's users are of course expected to be knowledgeable in this domain, first and foremost. So too are the systems analysts who aid in specifying the requirements for any new system. The required knowledge may be relatively broad or narrow, shallow or deep, according to the work supported, which often involves multiple individuals in different roles. The purpose of the information system is typically to inform its various users within such a work system, in support of their decisions and actions.^[20] Beyond their domain knowledge, users are typically trained in their interactive use of any new system, such that they understand how to navigate it, interpret its displays or other output, and provide needed data or other input. Ease of use is a major issue in successful implementation.

Notwithstanding such training, research suggests that new information systems are unlikely to deliver full value to organizations and their users until they have been assimilated into the work practices they support.^[21] Repeated "learning by doing" is needed before users "appropriate" a system into their preferred work practices. Moreover, with such assimilation, certain application knowledge will be tacit on the part of users, demonstrated primarily in their competently doing the needed work. Users will also typically find new uses of information systems, beyond those envisioned by system designers. Systems are thus substantially "reinvented" through their use. Importantly, then, application knowledge is ultimately inseparable from the work practice that gives it meaning.

Technology Knowledge

Technology knowledge pertains to the computer-based platforms on which applications are built. This includes the computers, communications, storage and other devices, and the system software that operates these resources. Among the jobs associated with building and maintaining

these platforms are those of the system programmer, the network manager, the data base administrator, and the Web master. Technology knowledge also pertains to basic tools and resources drawn on by those engaged directly in application development; these are sometimes integrated and provided in the form of a "work bench."

The most basic aspects of a computer-based platform are its suitability, capacity, and reliability in supporting applications. Growth in firms and their information systems makes capacity planning a vital task. Also important are standards.^[22] Where the platforms are in wide use by organizations, the associated technology knowledge is similarly widespread and more easily acquired in the marketplace when needed. Even more significantly, widely used platforms attract their own extensions, as vendors build new features for them roughly according to the potential market reached. This advantage extends to the application software employed in system building, where a wider variety of packaged systems will be readily available for standard platforms.

Development Knowledge

Development knowledge pertains to the application software, data model, Web or other interface, and human procedures that are specified, built or otherwise acquired, documented, tested, installed, and maintained over the life of an information system. It pertains further to the methodology used in this particular work.^[23] Principal jobs include those of the systems analyst, who in collaboration with prospective users specifies the functional requirements for the system, and the applications programmer, who in consultation with the systems analyst designs and codes the software to meet these specifications. Within the user community, "lead users" often represent the interest of their peers in the development activity, helping in particular with system implementation and needed training.

Project management knowledge for guiding implementation of systems is especially important, as system development work tends to be organized as projects. Senior developers of individual systems often work as project managers. Projects are typically managed according to their associated deliverables, schedule, and budget. Because of characteristic pressures on schedule and budget, a particularly important aspect of project management is attention to the quality of the deliverables as well as the avoidance of their expensive elaboration through "feature creep." While these issues have long been well known among professionals, they continue to bedevil most of those engaged in the work.^[24]

Management Knowledge

Management knowledge pertains to the management of information systems activities within the enterprise. Depending on the size of the organization, managers may

include: the data center or operations manager, the network manager, the applications development manager, the applications maintenance manager, and the executive in charge of the function as a whole, who in a large organization sometimes has the title of chief information officer (CIO). A primary responsibility of the CIO is the alignment of the information systems strategy with the broader firm strategy.^[25] Another is the staffing and organization of the function and the building of its expertise, as well as setting policy and contracting for external services. A third is the building of a reliable and adaptable network and technological infrastructure.^[26] Still another is the management of the application systems portfolio, and the allocation of resources between maintenance of existing systems and the development of new or replacement systems.^[27]

One highly visible issue in recent years has been the outsourcing of the information systems function, in whole or in part. "Off-shoring" is much discussed, in particular. Much system development work in the most developed nations is now carried out in countries with more attractive wage rates and growing technical competencies, such as India and China, and certain eastern European states. Exactly which work should be outsourced and which should not remains controversial.^[28] The data center itself is a prime candidate for outsourcing. In general, programming is more easily outsourced than is systems analysis, which requires a deep grasp of the work context. The long-run implications of this shift in work are globally significant for the world economy, beyond the immediate challenges and choices faced by today's managers.

AN EVOLVING FIELD

Today, the information systems field of study and practice remains an evolving one marked by continuous change. Notwithstanding its accomplishments to date, the field faces numerous challenges. Its various professional associations, publications, and research firms and consultancies will play important roles in guiding future information systems developments.

Professional Associations

The International Federation for Information Processing (IFIP), founded by 13 national computer societies in 1960, established Technical Committee 8 (TC8) on Information Systems in 1966. TC8's aims are "to promote and encourage interactions among professionals from practice and research and advancement of investigation of concepts, methods, techniques, tools, and issues related to information systems in organizations."^[29] TC8 now includes eight working groups, the first of which, WG8.1, Design and Evaluation of Information Systems, was established in 1976, and the second of which, WG8.2, The Interaction of

Information Systems and the Organization, was established in 1977.

The International Conference on Information Systems (ICIS) is the premier academic research conference in the field, held annually since 1980. The Association for Information Systems (AIS) is the leading academic association, established in 1994 to bring IS academics together from around the world. It sponsors ICIS and three regional conferences annually: the Americas Conference on Information Systems (AMCIS); the European Conference on Information Systems (ECIS); and the Pacific Asia Conference on Information Systems (PACIS). Among its other activities, AIS publishes the *Journal of AIS* and *Communications of AIS*, and sponsors AIS World, an important Web resource for IS scholars.

The IS field today also maintains its important roots in the allied fields of computer science, operations research, and management. The Association for Computing Machinery (ACM), founded in 1947, claims to be the world's oldest educational and scientific computing society and now serves professionals in more than 100 countries. Its many publications include the widely read *Communications of the ACM*, which features many articles of interest to IS professionals. Its interest groups include the Special Interest Group on Management Information Systems (SIGMIS). Among ACM's most important contributions has been its issuance since 1972–1973 of curriculum recommendations for academic programs of study in information systems.^[30]

The Institute for Operations Research and Management Science (INFORMS), formed in 1995 from two earlier societies, is now an umbrella association of operations for research-oriented academics and practitioners that includes an Information Systems Society among its 10 societies. It also publishes the leading journal, *Information Systems Research*, begun in 1990.

The Academy of Management includes an Organizational Communications and Information Systems Division among its some two dozen interest groups and divisions.

Among practitioners, the Society for Information Management (SIM), originally founded as the Society for Management Information Systems (SMIS) in 1969, serves IS executives and professionals through a series of chapters located primarily in North America. In its early years, SIM was instrumental in advancing the MIS concept among executives.^[31] It also established the leading journal, *MIS Quarterly*, in 1977, in cooperation with the Management Information Systems Research Center (MISRC) of the University of Minnesota, which now publishes it exclusively, while SIM members receive it as a membership option.

Publications

Today, a wide variety of publications reaching both general and specialized audiences feature articles on information

systems. Business periodicals such as *The Economist*, *Business Week*, and the *Wall Street Journal* provide good coverage for the general reader. In addition to those already mentioned, other notable academic journals devoted to information systems include the *Journal of Management Information Systems*, the *Journal of Information Technology*, *Information and Organization*, and the *European Journal of Information Systems*. Practitioners in the field find the periodicals *Information Week*, *CIO Magazine*, and *Computerworld* important for following current events in the fast changing technology industry.

Research Firms and Consultancies

Practitioners are also served by a number of market research and analysis firms such as Gartner Group and Forrester Research, which offer assessments of new technologies and their markets, as well as international consultancies such as Accenture, Deloitte, Tata Consulting, and IBM Business Services, which are widely engaged in “system integration” activities, and which further help to spread “best practices” in information systems among firms. These research firms and consultancies also serve as “thought leaders” in the institutional environment within which “organizing visions” for the application of new technologies originate and serve to guide adoption and diffusion.^[32]

SOCIAL ISSUES

Information systems are associated with several ethical and social issues inherent to their nature, design, and use.^[33] The authors Kenneth and Jane Laudon identify five moral dimensions to the Information Age: information rights and obligations; property rights and obligations; accountability and control; system quality; and quality of life.^[34] We consider each briefly.

Information Rights and Obligations

Every information system poses questions of information rights and obligations, often for both persons and organizations. Rights to individual privacy are particularly salient in an age where much organizational data are gathered about customers, employees, and others, and too where those who do business on the Internet can easily gather individual data generated through Web site visits, for subsequent use in targeted advertising, for instance. Throughout the world, businesses thus now operate under various laws intended to safeguard individual privacy. In Europe, privacy protection is stronger than in the United States, as businesses there are generally prohibited from using information about persons without their prior consent. In the United States, most businesses make their privacy policy known to their customers, who

must typically then “opt out” if they wish to avoid having certain of their data shared with others for marketing purposes. As many U.S. customers do not take this opt-out step, nor do many probably even consider it, their individual data are widely shared in marketing.

Privacy concerns are of course also inherent to surveillance schemes which employ information systems. Firms may closely monitor the work of their employees, sometimes stepping over the line into private lives. Governments of all kinds are notoriously tempted to keep more than close track of their citizens as well as others, as they seek to repel threats both real and imagined.

Property Rights and Obligations

Information systems also pose challenges to certain intellectual property, which increasingly is represented in digital form, and which a firm may seek to protect as a trade secret, or through copyright or patent. Both the software and the data associated with information systems are likely to be associated with property rights, as are other digital products such as music or video or text recordings that offer entertainment and education, and which are commonly organized, managed, and distributed via information systems. An interesting illustration today is Apple’s iTunes business, which is entirely digital in nature, and which distributes music for download by consumers on demand, much of it under protection of Apple digital rights management (DRM) software that is itself a protected asset, with several different parties sharing in the resulting revenues.^[35]

Accountability and Liability

Information systems also pose new issues of accountability as well as liability, where harm results from their employment. When things go massively wrong, e.g., when an operating error at a bank results in failure to automatically deposit customer paychecks in a timely manner, it may be difficult to disentangle the reasons behind the debacle. Often we are told that a software bug was the problem, and indeed this is often the case. But because information systems are based substantially in HCI, whether it was human error or a software bug or a problem in data exchanged or the interaction itself, or more broadly a problem in the design or execution of the work being carried out, or a failure in the oversight and management of overall system quality, blame can be difficult to fix and hence may sometimes be misplaced to avoid accountability and in some cases liability.

System Quality

As just suggested, system quality is a broader issue than one of minimizing the bugs in software. Organizations bear a responsibility to attend to the broader quality of

their information systems. Research suggests that notwithstanding this responsibility, few firms systematically assess the quality of the data associated with their systems, for instance, even though data errors are known to be rather commonplace.^[36] One area where attention to data quality is typically enforced is in business accounting, where external auditors provide independent oversight. However, even here, where the financial stakes may be high, system quality may be compromised through inattention or misguided cost cutting measures. The reality is that system quality is achieved only at the cost of means that ensure it.

Quality of Life

Lastly, information systems have long been associated with a variety of quality of life issues, especially as they pertain to system users.^[37] Among ongoing issues are the extent to which power is centralized or decentralized through systems, the increased difficulty in maintaining a balance between individuals' working and private lives, new vulnerabilities to crime and abuse such as spam, the reengineering of work and its consequences for job skills needed, characteristic health problems such as repetitive stress injury (RSI), the problem of electronic trash disposal, and social inequities in access to technology, as illustrated by the much discussed problem of the "digital divide" in U.S. schools. In short, information systems have come to have pervasive consequences for the quality of our individual and social, and private and public lives.

CONCLUSION

In the relatively short span of several decades, information systems have emerged to be a dominant feature of modern organizational life, with broad implications for people everywhere. The future promises to extend this story. Currently, organizations throughout the world are rapidly building their presence on the Web, and moving from merely offering certain published content, sometimes disparagingly referred to as "brochure ware," to engaging in basic transactions with their customers, suppliers, and other partners. In short, more organizations are doing everyday business on the Web, popularly termed "electronic commerce," underpinned by information systems that make this possible. New businesses are at the same time originating everywhere on the Web to provide the basic infrastructure for doing this business (Google, eBay, and Amazon.com are widely known examples), as well as to offer new distribution for digital content in the realms of education and entertainment, in particular, attracting more traffic to the Web and thus broadening and deepening its user base, making it more appealing for social networking and advertising. As of this writing, the concept of "Web 2.0" as a social space that enables new forms of

organizing is the latest new vision to capture the fancy of the field.^[38]

ACKNOWLEDGMENTS

I have benefited from several excellent textbooks in preparing this entry and have incorporated them in the references section. They provide good resources for additional reading. I am also grateful to Ephraim R. McLean and an anonymous reviewer for their comments on an earlier prepared version.

Information Systems Failure

Chris Sauer

Saïd Business School, University of Oxford, Oxford, U.K.

Gordon B. Davis

Carlson School of Management, University of Minnesota, Minneapolis, Minnesota, U.S.A.

Abstract

Information systems (IS) failure is characterized as one particular form of evaluation of IS performance. It is multidimensional and relative to stakeholder interests. The objective of failure studies is to assist understanding of how to achieve success. This entry reviews recent performance data to assess the magnitude of the issue. It traces historical developments in the understanding of failure. It examines various changes that have affected perceptions of IS performance. It identifies a number of cognate subliterations whose emergence recently signals a growing maturity of analysis. The entry proposes a framework by which to understand the historical development of academic research in this field. Finally, it offers some key conclusions for academic research and for practice.

INTRODUCTION

Information systems (IS) failure has been a focus for study and action for both practitioners and academics since the late 1960s.^[1–3] Most organizations have struggled to deliver systems that work and deliver benefits. Practitioners have wrestled with these difficulties in their workplace and the public has experienced systems' shortcomings in trying to use them. Nobody seriously doubts that failure has been and continues to be a problem to be tackled.

The focus on failures does not mean that there are two classes of applications—those that succeed and those that fail. There is a continuum of results ranging from clear and utter failure to very high success. There are applications that are barely acceptable but survive, and there are applications that are mildly successful and fail.

This entry reviews only one end of the spectrum of results: applications that are failures. The meaning of “information system success” is a significant issue^[4] in itself and is not the purpose of this entry. Information system failure and information system success are not simply opposites.^[5] To achieve success, it is necessary to remove causes of failure, but doing so may not be sufficient for a successful outcome. More broadly, the study of failure is justified by the belief that, just as the study of cognitive malfunction can help us understand good mental functioning, it casts light on what it takes to achieve success. Understanding “information system failure,” therefore, represents one but only one part of what needs to be understood for the effective design, implementation, management, and exploitation of an information system.

Where once “failure” was viewed as an almost objectively identifiable state, today there is wide recognition that

it is an evaluation based on an assessment of some dimension or dimensions of performance relative to goals, targets, or expectations. Failure in one dimension, say a budget overrun, may be more than compensated for by success in another dimension, say timely implementation. And, as what is regarded as performance has itself changed, so the domain of failure studies has evolved. For this reason, it is appropriate for this entry to take an historical approach.

In this entry, the study of failure is treated as one important branch of the study of IS performance. Our overall objective is to provide a rigorous basis by which to understand what may be meant by “IS failure” and a set of signposts to appropriate analytical approaches by which to develop greater insight into the phenomenon.

We start with a review of recent performance data. We examine the various changes that have affected perceptions of IS performance. We identify a number of cognate subliterations that have developed over recent years and which signal a growing maturity of analysis. We provide a framework by which to understand the historical development of academic research in this field.

THE SCALE OF IS FAILURE

Prior to 1995, most assessments of the scale of IS failure were informal in nature and anecdotally derived. In 1995, the Boston-based consulting group, Standish, published its findings under the banner headline, *Chaos!*^[6] Based on data about more than 3000 IS projects, it reported that 31% were abandoned without being completed. These it dubbed failures. Some 53% failed to meet at least one of its budget, schedule, and scope targets. These were dubbed challenged projects. The remaining 16% that hit all three

targets were deemed successes. These have since become the most widely cited failure statistics.

Every 2 years since 1995, the Standish Group has released updates on these figures. Figures released for 2004 revealed 29% hit all targets, 53% were challenged in missing at least one target and 18% were classified as failures.^[7] In summary according to the Standish Group figures there has been sustained improvement but there remains continuing cause for concern. While some question the Standish survey and analysis methodology,^[8] raising questions about the accuracy of the detailed findings, in 1995 few doubted the broad conclusion that most IT projects seriously underperformed. Subsequent surveys reinforced the point (e.g., Taylor).^[9] Likewise today, more than a decade later, the improving trend they identify is commonly acknowledged.

Less clear is the extent of the improvement and therefore the extent of the outstanding problem. To measure this, it is better to use percentage variance from targets.^[10] Otherwise we cannot tell whether “challenged” projects are more or less challenged over time. Sauer et al.^[10] also argue that an absolutist definition of success by which any variance however small assigns a project to the challenged category is too strict. In most cases a small budgetary or schedule overrun is of negligible significance. Using statistical clustering techniques, they show that there is a significant gap between the majority of projects that miss their targets by just a small percentage margin and those that are clearly failing on a more substantial scale and that therefore it is worth tolerating some small margin of variance. However, even on this more optimistic assessment, at least one-third of all projects fall well short of delivering on all their targets.

THE EVOLUTION OF IS PERFORMANCE

In the previous section we saw that IS performance has changed over time and that the metrics by which performance in general and failure specifically are identified are not definitively agreed. In this section we explain how the phenomenon itself has changed and explore the implications for the measurement and identification of failure.

We start with a distinction between systems and systems projects. In the 1960s and 1970s, the system and the project were often conflated. If a system failed, say because it did not deliver the functionality its users wanted, it was usually the case that the project had been troubled too and vice-versa. This was also a period in which computer malfunctions were common resulting in breakdowns ranging from the everyday experience of the computer being “down” to catastrophic loss. Such malfunctions have been extensively cataloged by Peter Neumann in his *Inside Risks* column in the *Communications of the Association for Computing Machinery* over many years.^[11] While more reliable hardware and standardized and re-usable software

have removed many causes of such malfunctions, they remain a continuing hazard (e.g., Hodgson)^[12] but today are rarely such as to cause abandonment of a system.

With the advent of rigorous project management disciplines it has become normal to detail precise targets, in terms of budget, schedule, quality, and scope. These are essentially internal measures that in principle are within a project manager’s capacity to control. It has become apparent therefore that a project may be successful in meeting its internal targets yet not deliver beneficial business outcomes. More recently, as the role IT plays in organizations has become critical to their functioning as exemplified by the widespread adoption of e-business for front office business functions, there have been cases of projects failing to hit budget and schedule targets but nevertheless delivering highly desirable business outcomes. The distinction between the system and the project is therefore both conceptually sensible and practically relevant.

What counts as an information system and therefore what is involved in an IS project has changed over time and this has affected the measure of performance. Purpose-built systems have given way to standard packages (so-called enterprise software). Projects are therefore more about system integration than software development. This has led to two important consequences. First, it has engendered more ambitious, more complex projects that combine packaged functionality to an extent that was previously unimaginable. Second, because the software is prewritten, it has encouraged organizations to direct project managers’ efforts to implementation, business process change, and value harvesting. This latter has extended project scope considerably and turned managers’ attention to an external target, the business value achieved by investment in an information system.

This shift in emphasis from internal to external targets, from assessing performance against process to performance on outcomes, is appropriate from a commercial investment perspective. It is, however, problematic to measure because IT systems do not deliver value on their own, they do so through organizational and business process change.^[13] Even if the value itself is measurable and measured, and it often is not, the extent to which that value derives from the information system may not be possible to determine. Further problems include the question of when to measure value outcomes. Often immediately after implementation, organizational performance suffers^[14] before recovering and improving. But the longer the lag between implementation and outcome measurement, the more space there is for extraneous variables to affect the value outcome.

Thus far in this section, we have examined how IS performance has evolved in practice. We now turn to how its conceptualization has evolved academically. A significant breakthrough came with the explicit recognition that “failure” is an evaluation not an objective description. Lyytinen and Hirschheim^[15] developed a

new pluralist concept of expectations failure which explicitly recognized that failure was a judgement relative to expectations and that expectations vary among stakeholders. This pluralism opened the way to the possibility that a single system or project could be a failure relative to one set of stakeholders and a success relative to others. It also triggered discussion of whether some stakeholders' expectations might weigh more in arriving at a single overarching evaluation—this is “on balance” a failure notwithstanding some less important stakeholders viewing it as a success. Several responses have emerged. Some have tried to identify apparently unequivocal failures such as abandoned projects (e.g., Johnson^[6] and Ewusi-Mensah^[16]) though it has been argued that even an abandoned project might be viewed by some stakeholders as a success if an objective was to learn about a new technology, test customer responses, or experiment in some other way.^[17] Sauer^[17] advanced an uneasy compromise that recognized the plurality of stakeholders but recognized that a distinction should be made between supporters of a project and those who were uninvolved or active opponents. Others have finessed the issue by focusing on specific dimensions of performance such as budget and schedule variance without using explicitly evaluative terminology.^[18–20] In doing so, by the very nature of their choices of performance dimensions to study including the recent introduction of business value as an outcome measure, they can be argued to implicitly favor the expectations of traditional stakeholders such as the owners and managers of businesses. By contrast, others have embraced pluralism and absorbed it into new theoretical approaches such as Actor-Network Theory which we discuss below.

We can summarize this section by saying that the conceptualization of failure has evolved and matured in three ways. The first has been the distinction between systems and projects. The second has been the expansion of the legitimate scope of IS projects with consequences for what dimensions of performance are assessed. The third has been recognition of the evaluative nature of “failure.” This has surfaced disagreement as to which stakeholders' expectations should receive priority. This is a political disagreement rather than one of facts or data. Those who believe that owners and manager as the agents of owner matter more will adopt a more traditional view of failure where as those who believe that employees, the public, and others have just as much right to their interests and expectations being respected will take a more egalitarian and pluralist position.

EMERGING COGNATE LITERATURES

A further manifestation of the maturation of our understanding of IS failure has been the emergence of several cognate literatures. We briefly discuss in turn risk, partial abandonment, expectation management, escalation, and drift.

Risk as discussed in the extensive IS and software engineering literatures relates to failure by seeking to identify what may be conducive to failure, how to assess its probability and impact, and how to manage it. It is about the probability of failure in some shape or form. It has typically been strongest at identifying sources of risk such as starting conditions or behaviors that give rise to failure.^[21] Such studies usually result in extensive lists. The usual suspects thus identified typically include: unclear objectives, uncertain requirements, inadequate project management, too little user involvement, and shortage of top management support. The literature has been less convergent in its focus on risk assessment. While there is an in-principle agreement that risk consists of two elements (the probability of some outcome and its impact), the determination of what the actual risk amounts to has proved problematic. Some have focused on the impact of total failure as represented by abandonment,^[22] while others have looked at specific dimensions of performance such as running over schedule or budget. Some studies while recognizing that impact is an element of risk focus principally on the probability of underperformance.^[10] The management of risk, and therefore the prevention of failure, has principally consisted of attending to risk factors to prevent their occurring or mitigating their effect when they do occur.

A further set of cognate studies is that on partial abandonment.^[23,24] This recognized that a common strategy for coping with underperformance, such as projected schedule or budget overruns, or unanticipated events is to descope, which is to say abandon, some elements of a project. It advanced our thinking by showing that what might simplistically be viewed as a symptom of failure can also be an instrument for preventing failure or further failure. Failure is not a simple cut and dried function of any single indicator.

The focus on expectations failure brought into focus the idea that success and failure are a function of the targets as well as the delivery and performance of a system. That is to say that one way of preventing failure is to manage expectations closer to what is realistically achievable. Ginzberg^[25] pioneered this notion. It has received limited attention subsequently^[26] although, influenced by Danish research,^[27] the United Kingdom's Office of Government Commerce today mandates that all projects control for “strategic optimism,” the tendency to set expectations unduly high.

A more abundant cognate literature has been that on escalating commitment to a failing course of action. It addresses the key question of why organizations do not cut their losses sooner. Inspired by a substantial corpus of work in Organizational Behavior,^[28–32] and recognizing that many IS projects have been characterized by sponsors pouring in good money after bad to projects that would ultimately fail, researchers have explored the applicability of existing theory and sought to adapt it to the IS failure phenomenon.^[33–35] While escalation of resourcing

is indeed a common feature of projects and existing research enriches our understanding of why it occurs, its practical value is limited by the question of whether we can adequately recognize failure in advance and the extent to which escalation often genuinely sustains a project that would have collapsed without it.

Finally, the “drift” literature introduces a further recognizable phenomenon associated with project performance and which may often either result in failure or substitute for it. Instigated by Ciborra,^[36] the idea is that objectives are not immutable fixtures in a project but are subject to organizational politics that often neutralizes them without radically reviewing the case for the project or system. The resultant drift leaves organizations with IS investments that do not meet their real needs but which are not subjected to the scrutiny that might lead to their redevelopment or abandonment. Empirical exploration and development of this phenomenon is in its infancy.^[37,38]

So, while risk research has worked to connect failure to management practice with a view to reducing its probability, the other cognate literatures have functioned to situate failure within a more sophisticated understanding of organizational contexts and what counts as success within them. Specifically, partial abandonment recognizes that failure on one dimension of performance, namely scope, may be sacrificed to achieve better performance on another such as budget. Expectation management extends this more realistic approach to what will count as good or bad performance by recognizing that targets in the form of stakeholder expectations are legitimately subject to influence and change. Escalation theory is an inverse of partial abandonment in that it shows why larger and larger overruns on resourcing such as budget may be promoted in the interests of achieving scope and outcome expectations, and how this can be dysfunctional. The focus on drift brings a recognition that not all systems and projects are subject to clear-cut evaluations on a continuing basis and that over time objectives and expectations may be diluted through organizational political processes without any re-evaluation occurring. Failure studies if they are to embody a realistic and sympathetic understanding of the richness and complexity of organizational life must embrace the insights that these cognate studies have brought to the table.

APPROACHES TO UNDERSTANDING IS FAILURE

As our understanding of the concept of IS failure has evolved, so too have our approaches to analyzing the causes of failure. We can distinguish three broad approaches. At one extreme, we have static analyses based on the identification of factors that predispose to failure. At the other extreme, the emphasis is on dynamic analysis and the explication of processes by which failure comes about. Bridging the two is the interactionist approach.

Static Approaches

Static, factor-based approaches were at their most popular in the early days when failure was seen more as an objective phenomenon. It was easy then to ask what caused failure and to look for factors that “determined” failure. What were seen in retrospect as common features of failures rapidly became accepted as causes which if rectified would lead to improved performance and outcomes. Research was undertaken to validate this view (see Larsen^[39] for a compendious review of factors identified in the research).

Within this class of approaches, several versions developed emphasizing different perspectives and therefore different failure factors. We identify three here: the technological perspective, the organizational/cultural perspective, and the political perspective.

The technological perspective

A distinguishing feature of the technological perspective has been its strong focus on the technology elements as the most important considerations for an information system (and often the only components to consider in building the system). The efficient processing of data and the efficient operating of hardware and software provide the goals around which people and procedures are to be organized. Studies in this perspective have often embodied two important assumptions. The first is that technology in all its forms (including hardware, software, and databases) is considered to be “good.” The “imperative” in technological imperative refers to the inevitability of technology to “compel” acceptance, use, and conformity to it.^[40] Any resistance to a given technology is regarded as merely an irrational, impermanent phenomenon. The second is that implementation of technology alone is sufficient to secure organizational benefits. Together these assumptions conspire to exclude other factors as relevant to success and failure.

The technological perspective therefore implies a dominant focus on formal development procedures for systems analysis and design, the purpose of which is to build or upgrade an information system. There are four major phases in the development cycle. The first phase consists of requirements determination to identify the output of the hardware–software system and the data to be input and processed. The second phase is conceptual design to create a “logical” or conceptual blueprint for the system. The third phase is the “physical” or implementation design for specific software and hardware needed in the information system. Building or upgrading the hardware–software system follows. All formal system development methodologies, as well as the tools of computer-aided software engineering that implement them, involve these four phases or variations of them. The technological perspective tends to underlie not only most development methodologies but

also most textbooks on programming, systems analysis, systems design, database management systems, and telecommunications.

In the technological perspective, the diagnosis of an information system failure focuses on a hardware failure, a software failure, a data failure, or any combination of these. The chosen hardware platform may have defects in its manufacture or configuration. The software may suffer from poor design or error-prone construction. The database may harbor inconsistent, incomplete, or outdated data. Since the technological perspective assumes that users can correctly and completely define processing requirements, a failure in the system may also arise because the requirements were specified incorrectly or incompletely. For instance, the information system could lack the capacity to support the processing load if this were not specified correctly.

In general, the remedy for a potential information system failure based on the technological perspective view is for people to conform to the development cycle procedures and to follow processes specified for operation of the system with its hardware, software, and database. The technological perspective requires that people (analysts, designers, managers, programmers, end users, etc.) do or redo the steps of the systems analysis and design correctly. Any failure by people to respond appropriately (e.g., users who do not willingly participate in the requirements determination step, users who resist using the installed system, designers who neglect to install adequate backup procedures, or designers who themselves resist using computerized tools) is seen as a failure of developers and users and not a failure of technological solutions to organizational problems.

The organizational/cultural perspective

By contrast with the technological perspective, in the organizational/cultural perspective it is technology that must adapt to people and to organizations. An organization, in this view, is more than a collection of people. An organization is a structure of roles and rules in which the rules delimit the aims, resources, prerogatives, actions, and behaviors allowed to the person occupying a role. The "culture" in organizational culture refers to the organizational members' shared knowledge or shared understanding of the structure of roles and rules. As successive generations of participants enter, pass through, and leave an organization, its structure of roles and rules continues to exist and to evolve slowly. Upon entering an organization, an individual becomes subject to the organization's structure of roles and rules. Different individuals, when placed in the culture, tend to display similar actions and behaviors. Thus, the culture is the ongoing realization, albeit often partial, of the formal organizational design. An information system application that reflects the desires of one person or a group of people but ignores

organizational culture is unlikely to fit the way the organization works.

Preceding the installation of a new information system or the upgrading of an existing one, the organizational/cultural perspective emphasizes the existence of beliefs and assumptions shared among the organizational members, about what computers do, how technology affects jobs, why the current information system is being upgraded or replaced, and so forth. When held by people in contemporary organizations, these beliefs and assumptions operate much like myths, metaphors, and magic among "natives" in preliterate societies.^[41] In this view, an information system is but one among many artifacts crafted by organizational natives for use in their daily activities and rituals. Hence, in the organizational/cultural perspective, an information system failure is a failure of this artifact to serve and be compatible with the activities and rituals of the organizational natives.

In the organization culture of information technology, a poor fit between an information system (the hardware, software, and data) and the organizational culture is conducive to an information system failure. A framework useful for identifying a poor fit between information system and organizational culture specifies seven categories of shared beliefs and assumptions that can be violated by systems:^[42,43]

1. Shared beliefs and assumptions about innovation and action (e.g., are original and creative behaviors "good?").
2. Risk taking (e.g., is the norm to be proactive and take responsibility for one's own actions, or to be reactive and avoid responsibility?)
3. Integration (e.g., how much importance is placed on communicating and cooperating with other organizational members?)
4. Top management contact (e.g., does top management customarily relate to subordinates by being affirming or openly critical?)
5. Autonomy in decision making (e.g., are organizational members allowed, encouraged, expected, or trusted to make decisions on their own?)
6. Performance orientation (e.g., are the criteria for compensation, job security, and job promotion concretely established, explicitly known, and actually used?)
7. Reward orientation (e.g., do rewards take the form of a "carrot" or "stick?")

In this framework, the failure potential for an information system increases with the number of categories of cultural assumptions with which the information system is incompatible, as well as the extent of the respective incompatibilities. For instance, consider an information system that makes an assumption that there is open sharing of data across the organization's different divisions (integration) and that new users of the system will take responsibility

for the decisions that they make with the help of the information system (risk taking). If the organizational members share a norm in which each division guards its data as a valued resource and if the organizational members share, as an accepted practice, the custom of “blaming the computer” for their bad decisions, there is a significant threat of failure for the new system. Any additional incompatibilities between the information system and other shared beliefs and assumptions would increase the threat of an information system failure.

To prevent or to remedy an information system failure, the organizational/cultural perspective requires that the information system be designed and adjusted to respect the constraints that the organizational culture imposes. A strong proponent of this view will maintain that an information system is an artifact crafted to serve the activities of an organization, and therefore the information system should always conform to the organization, rather than vice versa. In other words, a proponent of the organizational culture view may take the position that altering an organizational culture to fit an information system, even if possible in the long run, is a dangerous course of action.

The organizational/cultural perspective extends the technological perspective by bringing in organizational/cultural factors. It also introduces the idea of a fit between the technology and the organization/culture. However, it continues to assume that the important challenge is to establish the right conditions in terms of getting two sets of factors aligned with each other.

The political perspective

The political perspective extends the organizational/cultural perspective by introducing power as the real basis by which organizations work. Power is the ability of a person, group, or organizational unit to overcome resistance or opposition to achievement of its ends; politics is the exercise of this ability.^[44-46] In this view, activities that accompany the development, implementation, and use of an information system provide an arena in which a person, group, or organizational unit can exercise power, whether or not the ends for which the power is exercised bear any relevance to the purposes that the information system is ostensibly said to serve. Success or failure of the information system relative to these ostensible purposes is secondary to the achievement of the power objectives.

In a classic case study of an information system implementation,^[47] a new information system threatened to alter the power between the corporate accounting group and divisional accounting personnel. The system was designed to allow the accounting group at corporate headquarters immediate access to data belonging to the accounting group in each of the company's different divisions. In the existing procedures, each division controlled its own data (stored in thick manual ledger books), and corporate accounting could only obtain it through reports

prepared by division accountants. Built into the design of the new information system was a presumption that there should be a different distribution of power relative to the division data. This design was contrary to the existing power over the data. In the technological imperative view and the organizational culture view, resistance to the proposed system could be explained as opposition to a more efficient system or opposition to changes in the culture of corporate versus division roles. In the political perspective, the efficiency considerations or role changes were secondary; the main objective of the system for the corporate accountants was political. They wanted to disrupt the existing balance of power in the organization and introduce a new balance of power based on data access that favored the corporate group.

In the political perspective, the failure potential for an information system application increases if it violates the constraints imposed by the organizational distribution of power. In some cases, an application will be allowed to succeed only if it supports the political agenda of a powerful group within the organization. IS may be used explicitly to change the distribution of power in an organization; in such cases, the design of the system is a secondary factor in success or failure. The major issue is the effectiveness of change agents in negotiating redistribution or organizational power.

To prevent or remedy an information system failure due primarily to strong political opposition, the political considerations must be surfaced and negotiated. Political considerations may be somewhat hidden; surfacing them through high-level discussions allows the effect of the system to be dealt with in the context of high-level goals of the organization. An explicit understanding of the effect of the system on the relative power of the organizational participants may allow negotiations and compromise. In the absence of such compromise, political opposition to a system may be sufficient to cause failure.

The political perspective has sometimes been operationalized in research in terms of the fit between an information system or project and the power structure. Such operationalizations fall under the factor approach. Others however have recognized that power can be renegotiated and as such the processes by which IS are treated affect their success or failure.

Interactionist Approaches

Interactionist approaches bridge the step from factors to processes. In accepting that factors may influence each other, they implicitly introduce a temporal element to the analysis of failure. For example, a factors analysis might identify inadequate involvement of business users in requirements specification and user resistance as critical causes of failure. The interactionist recognizes that the user resistance may be a function of the lack of involvement. In turn, perceived user resistance may deter

technologists from consulting the users. The causes of failure develop and harden over time. Implicitly, such approaches recognize that the different factor approaches embody important elements that may contribute to a comprehensive analysis of failure. We briefly describe two such approaches: the sociotechnical perspective and the exchange perspective.

The sociotechnical perspective

In the sociotechnical systems view, an information system is more than a technical system of hardware and software. An information system is a social system that uses information technology.^[48,49] Failure is not a failure of the information technology alone or the organization alone, because there is a strong interaction between the two. The same information technology will exhibit different properties when used in different organizational contexts. Sociotechnical theory^[50] predicts that optimizing only the technical system or optimizing only the social system will lead to information system failure. To avoid failure, neither system can be managed separately from the other.

The interactive effects between the social system and the information technology have a parallel in the chemical difference between mixtures and compounds. The properties of a mixture are simply a combined set of the respective properties of the individual elements that constitute the mixture. The reason is that the elements in a mixture do not react to one another; their respective properties remain intact. However, the properties of a chemical compound are different from the respective properties of the constituent elements. The reason is that the elements react to one another; their respective properties are replaced by the new properties of the compound entity. In this analogy, an information system is more like a compound than a mixture. Its constituent social system and information technology react to one another, so that their properties in combination are different from their properties in isolation.

In the sociotechnical view, failure potential is increased by development processes and procedures that do not integrate both social and technical considerations. In sociotechnical development, the future users of the system specify important job and work design considerations. There is a joint effort involving both users and technical personnel to consider alternative information system technical designs and select one that achieves a reasonable trade-off between job design and technical efficiency. Dominance of technical considerations increases the probability of failure due to user resistance. The sociotechnical approach recognizes the fact that user resistance can cause a technically well-designed system to fail and user enthusiasm can cause a somewhat mediocre technical design to succeed. These dynamics are the basis for a process that looks for the best combination of technical and social factors.

To prevent or remedy an information system failure, the sociotechnical view specifies a sociotechnical

requirements and development process. Users are empowered with sufficient information to be effective participants in design discussions and decisions. Obtaining commitment by users to make the system succeed is an essential part of the process.

The exchange perspective

The exchange perspective^[17] develops the sociotechnical perspective in one specific direction. It emphasizes one critical basis of interaction, viz. the creation and sustaining of a balanced exchange between a project team or those who manage an information system and the key supporters of that project or system. It argues that projects and systems fail if two conditions obtain:^[1] there are insufficient resources to continue developing or operating the system, and^[2] key supporters are dissatisfied.

This perspective sees systems and projects as needing a range of different forms of support from a range of stakeholders. Support can include material resources such as funds, equipment, space, practical support such as involvement in project processes, problem-solving, and management attention, psychic support such as publicly observable commitment, as well as organizational support in terms of politics and working the organizational system. Stakeholders who may be key supporters include senior management sponsors, operational users, end customers, the project team, and the supply chain. As supporters' levels of satisfaction may ebb and flow over time, the task of IS management and project management is one of maintaining sufficient levels of satisfaction to ensure a continuing flow of needed resources. Thus, for example, the project process can be seen as the challenge of marshalling the right resources to deliver sufficient progress and expectation of benefit that supporters will continue to provide those resources. If progress stalls, resources needed to overcome a hurdle may not be forthcoming resulting in further difficulties for the project and further damage to supporters' expectations. The project team may be able to break out of this vicious circle by actions that restore confidence such as bringing forward the delivery of some benefits or by actively managing supporters' perceptions. If on the other hand it is unable to break out of this vicious circle, the project will be set for failure. Projects can be seen as an ongoing complex interactive process where exchange is at the heart of the interactions.

Process Approaches

Since the mid-1990s failure analyses have emerged that focus more on a detailed examination of process and the search for patterns in process. They have tended to view success and failure outcomes as not determined by factors or even by interactions but as a function of a yet more complex account of the processes by which

multifarious influences affect projects and systems over time. As yet no single perspective has come to dominate the field. However, we shall give special attention to Actor-Network Theory because it has been widely employed in social studies of IS including failures, and because it encompasses ideas from numerous other perspectives.

From within the IS discipline, Newman and Robey^[51] enabled process analyses of failure through their more general articulation of the elements of process analysis, and Newman has applied it in his failure research.^[52,53] Outside the discipline, in the broad area of social studies of technology, a number of case studies have been published that have cast light on IS failure through detailed accounts of IS processes.^[54] This has then been brought back into the discipline by critical theory-oriented researchers such as Howcroft, Wilson, and Mitev adopting a social shaping of technology perspective and applying it to failures.^[55,56]

Actor-network theory

Actor-Network Theory has recently become a popular tool for analyzing IS failure.^[36–38,57–59] Actor Network Theory has a number of attractions. First, it is the first approach in many years to take a balanced position in relation to technology. That is, where for most researchers it has been accepted that technology is subservient to human/organizational objectives, Actor-Network Theory places technology on a par with other stakeholders. It then views the object of study, say a project failure, through the lens of the actor-network in which it is embedded. Humans, institutions, and technologies are among the stakeholders who populate the network and propagate influences through its nodes. In this manner, the complexity of the contexts within which IS failures occur is well represented. Further, one of the core ideas of the theory is that of breakdown. The essence of this insight is that when something appears to be functioning well we treat it as a black box. Only when it begins to fail do we start to unpack it to understand what is going on. Thus, for example, we can understand “drift” in these terms.

The limitations of Actor-Network Theory are that it is still evolving a set of concepts for general use. Early analyses using it have tended to be very complex and not productive of readily practical conclusions.

Conclusion: The Future of Failure

Ten years ago, the question arose as to whether the increased commodification of IT would lead to standard solutions to such an extent that the problem of failure might dissolve.^[60] The alternative scenario was that the strategic benefits of IT would be such that organizations would continue to seek to differentiate themselves and

would therefore continue to pursue distinctive, non-commodity solutions. The improvements in performance are noted earlier in this entry but the continued difficulties in achieving expectations suggest that elements of both scenarios have occurred. This suggests that the issues associated with understanding and preventing failure will continue to be highly relevant for the foreseeable future.

The challenge for research is to strike a balance between analyses that embody every causal constituent in a failure but where it is difficult to see the wood for the trees, and those that are simpler but which promise too much to the practitioner because they suggest that a relatively simple intervention will be sufficient to prevent failure. Having developed a growing maturity in our understanding it is easy for research to fall into the former category. It is this trick that Actor-Network Theory or alternatives will have to master if it is to be both academically successful and practically useful.

CONCLUSION: SUMMARY OF LESSONS ABOUT FAILURE FOR PRACTITIONERS

The entry has lessons for scholars and researchers. It also has lessons for practitioners. These can be summarized as follows:

1. The evaluation of success or failure for a project is not usually a simple “success” or “failure” or identification of a single reason for the result. Success or failure depends on the criteria being used, the stakeholders being considered, and the level of expectations.
2. Organizations respond to perceptions of failure in various ways. One response is abandonment. Other possible responses include escalation and revision of expectations.
3. The ideal lessons for practitioners would be a set of simple prescriptions to prevent failure and ensure success. The analysis of the failure research provides guidance but no simple list of prescriptions. A thoughtful practitioner seeking to reduce the potential for failure should consider both static factors that predispose to failure and the interaction of factors that may lead to failure.
4. Static causes. Three types of causes that predispose to failure and therefore should be considered as part of prevention measures are:
 - Technological. The focus in failure prevention and failure analysis is on correct and complete hardware, software, or data (or a combination of these technological elements). Today, these are the least common causes of failure.
 - Organization/culture. The focus is on a good fit between the system and the activities, rules, roles, rituals, and culture of an organization.

Political. The focus is on incorporating the effect of political power on design, acceptance, and use of a system.

5. Interaction causes. The focus on static causes may not be sufficient. Factors may influence each other. Two approaches to understanding and analyzing failure based on interactions are:

Sociotechnical. This analysis is based on the view that an information system is a social system that uses information technology. To avoid failure, the interaction of the two systems must be considered in the designs of both.

Exchange perspective. Systems and projects need forms of support from a range of stakeholders. Critical to avoiding failure is creating and sustaining a balanced exchange between a project team and key supporters.

6. An emerging view that is perhaps not ready for widespread practitioner use is to analyze the process by which a complex set of influences affect the way projects and systems develop over time.

ACKNOWLEDGMENT

This entry adds to and develops aspects of the entry on Information Systems Failure by Gordon B. Davis, Allen S. Lee, and Kathryn Nickles in the previous edition of the Encyclopaedia of Library and Information Sciences.

Information Technology Adoption

Conrad Shayo

Department of Information and Decision Sciences, California State University—San Bernardino, San Bernardino, California, U.S.A.

Abstract

Since the dawn of time, humans have relentlessly continued to develop and adopt various information technologies (ITs) to thrive successfully in their environment. Generally, the rate of adoption has depended on the adopter's perceptions of the ITs' net benefits. In this entry, we draw from innovation diffusion theory, and the DeLone and McLean IS success model to discuss the literature on IT adoption by individuals and organizations. Since the proliferation of newer and more powerful ITs is apt to continue unabated for many years to come, we suggest new ways of identifying, learning, and implementing new ITs.

INTRODUCTION

This entry provides a general overview of existing literature on new information technology (IT) adoption by individuals and organizations. The terms adoption, implementation, consumption, acceptance are used interchangeably. Also the terms information technology (IT), information and communication technology (ICT), and information technology systems (ITS), are taken to be synonymous. Organizational adoption looks at adoption by aggregates: viz. work groups, departments, directorates, strategic business units, and companies or corporations including intranets and extranets. Other aggregate levels such as industries, communities, national governments, and society at large are beyond the scope of this entry. We define adoption as the process by which an IT innovation is acquired, installed, and used to perform tasks in work-related environments. The rate of successful IT adoption depends on the adopter's perceptions of the ITs' relative advantage, compatibility, and complexity, as well as its triability and observability.^[1] We draw from innovation diffusion theory,^[1] and the DeLone and McLean Information Systems (IS) success model^[2,3] to discuss adoption at each level of analysis: individual and organization. Innovation diffusion theory uses the S-Curve to classify adopters of a new IT into innovators, early adopters, early majority, late majority, and laggards. The DeLone and McLean IS success model posits that successful IT adoption is mainly determined by: 1) the quality of the technology itself; 2) the quality of the information the technology provides; 3) the quality of the service provided by IT support staff; 4) continual usage of the IT; 5) user satisfaction from the use of the IT; and 6) the overall impact it will have on the adopting individual or organization.^[2,3] The citations used are only representative of existing literature, not exhaustive. The entry starts with the premise that IT has the potential of profoundly

transforming individual and organizational welfare. That IT offers both an opportunity and a challenge (i.e., opportunity to increase productivity and effectiveness and a challenge to keep the motivation of perpetually learning newer and sometimes complex disruptive ITs), and that, whether the adoption of IT occurs voluntarily, through sanctions, or by pressure from outside parties,^[4] it will have to eventually help the individual user or the organization meet stipulated personal, strategic, or operational goals. One key factor is that there will always be a constant cycle of breakthrough IT innovations that will inevitably dislodge previous, now moribund, innovations. The entry describes the unavoidable role of IT discontinuities in the adoption process, and concludes by suggesting that since the proliferation of newer and more disruptive ITs is apt to continue unabated into the future; there is a real need for individuals and organizations to develop new ways of identifying, acquiring, learning, and implementing new technologies. Individual and organizational lifelong learning, and coping strategies are two recent constructs that depict the essence of survival in an increasingly interdependent IT-networked society.

BACKGROUND

Why IT Is Important

It is an accepted fact that IT “will change the world more permanently and more profoundly than any technology so far seen in history and will bring about a transformation of civilization to match.”^[5] It is also accepted that IT has the potential of enhancing individual and organizational performance. Individual or organizational performance is measured in terms of the tangible and intangible net benefits resulting from the using the IT innovation. Information technology is defined here as

any system, product, or process whose underlying technology base is composed of computers (both hardware and software), workstations, and/or computerized communication networks of all types, including Local Area Networks (LANs), Wide Area Networks (WANs), Metropolitan Area Networks (MANs), intranets, Internet, robotics, and smart chips.^[6] Recognition of the potential of IT has led individuals and organizations to invest enormous amounts of time and money in IT assets. It is noteworthy that a worldwide IT expenditure of more than \$4 trillion is expected in 2009 alone.^[7] Information technology is now so pervasive that more than 55% of the workforce in the developed world relies on it to produce their goods and services.^[8] For example, today's banks and global financial markets could not function without IT. It is now fashionable to refer to our generation as the information society.

Role of IT Discontinuities

Information technology discontinuities are breakthrough innovations that significantly change the rules of competition in terms of how data/information are captured, stored, processed, and used by individuals, organizations, and entire industries. Such IT discontinuities threaten to disturb the mode of doing business in the industry and have led to the collapse of companies and industries that do not adopt.^[9] For example the current convergence of digital and telecommunication technologies such as the Internet, Peer to Peer, MP3, and cellular phone on the music industry may lead to the creation of an entirely new industry that delivers music on demand; anytime, anywhere. Companies in the CD, cassette tape, or boom box businesses will be forced to adopt before an impending doom befalls them. According to Anderson and Tushman,^[10] and

Utterback,^[11] as a general rule, technological innovations tend to have a life cycle of their own.

As shown in Fig. 1, for the IT industry, the cycle begins with a new IT invention or the arrival of a newer IT (e.g., the Apple Computer) that is a substantial improvement of the prevailing technology in the industry. An era of turmoil then sets in as the new IT replaces its predecessor. In this era, innovators and early adopters identify, purchase, and learn to use the new IT. At this time, entrepreneurs and IT developers continue to experiment with alternative designs and compete for market share (e.g., Apple vs. IBM PC). Finally a dominant design emerges as the industry default standard. The industry default standard emerges by offering a combination of features and services that allow adopters to make effective use of the IT at an affordable price. We think that this is probably the time when the early and late majority adopters purchase and use the proven IT. Then the innovation cycle enters an era of incremental change where the focus is on market segmentation and lowering costs (e.g., Workstations, Laptops, PC Tablets, Internet, PC). This era continues until the arrival of the next IT discontinuity. Schumpeter^[12] argues that technological discontinuities should be encouraged and that unprofitable methods, firms, and industries must be allowed to perish in order to release trapped resources for new enterprises.

Despite the evident opportunities offered by IT, such as increases in output or decreases in the cost of some inputs in specific organizations, there is no clear evidence at least in the United States that IT consumption has raised overall national productivity. For example, "profitability rates have been falling in U.S. industries in the last decade despite the new investments in information technologies."^[13] As such, much of the investment in new IT may not have led to successful results after all. Some of the cited reasons for non-adoption are inability to learn "how

Fig. 1 Information technology innovation life cycle.

to change organizations faster than humans naturally want to change,”^[13] technically deficient ITs that are threatening to its users, low user satisfaction from usage of the IT, and high knowledge burden requirement to master the technology. Others are: users getting information that is not necessary for decision making, low individual or organizational ability to recognize the value of new information and adopt it for productive ends, and lack of adequate means to realistically measure the costs/benefits of IT. In short, there is skepticism out there about how quickly one should adopt a new IT.^[13]

At the level of the individual firm, the problem will be to overcome the resistance to change, both by individuals who feel threatened by such changes and by those who doubt the potential returns available from the large investments necessary in the new technologies. At the national level, countries may become laggards if, for example, they fail to provide an IT infrastructure adequate to enable their firms to take advantage of the new ways of doing business, ways that shrink the effects of time and distance(p. vii)

This entry provides a general overview of existing literature on new IT adoption by individuals and organizations. The guiding questions are: What role do IT discontinuities play in the adoption process? Why do individuals or organizations decide to adopt or not to adopt IT? How can individuals and organizations know whether IT adoption

has been successful? Why does the adoption of IT occur at different rates?

The entry is divided into two parts. The first part identifies the general attributes of adoption of innovations and generalizes them to IT adoption. The second part discusses the rate of IT adoption based on Rogers' S-Curve.^[1] A conclusion is provided at the end of each of the two parts.

PART 1: ADOPTION OF IT INNOVATIONS

According to Rogers,^[1] the rate of adoption of an innovation (in this entry, any new IT is considered an innovation) depends on the perceived attributes of the innovation, the type of innovation decision, the communication channels used to advertise the technology, the nature of the social system in which the IT is implemented, and the extent of the promotional efforts of change agents (see Fig. 2).

Perceived Attributes of Innovations

According to innovation diffusion theory, the perceived attributes of innovations are *relative advantage*, *compatibility*, *complexity*, *observability*, and *triability*. *Relative advantage* is “the degree to which an innovation is perceived as better than the one it replaces” as measured by

Fig. 2 Variables determining the rate of adoption of innovations.
Source: From Rogers^[1] on p. 207.

actual monetary gains, convenience, enjoyment, and satisfaction derived from its use. The greater the relative advantage, the higher the perceived usefulness,^[14] and the better the rate of adoption of the innovation. Constructs similar to relative advantage found in the literature include: performance expectancy, outcome expectations, job-fit, and extrinsic motivations.^[15] *Compatibility* is “the degree to which an innovation is perceived as being consistent with the existing values, past experiences, and needs of adopters.” For example, the implementation of a new IT in a work environment that has had previous experiences with poorly designed systems is much harder than the implementation of a new IT in an environment that has had prior good experiences with a well-designed system.

Complexity is “the degree to which an innovation is perceived as being difficult to use.” The level of enjoyment one gets from using a new innovation is inversely proportional to the degree of complexity one encounters. The lower the degree of complexity; the greater the perceived ease of use of the innovation^[14,15] and better the rate of adoption. Theories of cognitive absorption stipulate that low complexity leads to heightened levels of curiosity, playfulness, personal innovativeness, and rates of adoption.^[16] *Observability* is “the degree to which the results of an innovation are observable to others.” Individuals may adopt a specific IT in order to gain recognition or make themselves indispensable. This is what the technology acceptance model calls social influence. *Triability* is “the degree to which an innovation may be experimented with on a limited scale before adoption.” Ability to pilot enables potential adopters to reduce uncertainty and become acquitted with the new innovation.

A number of research studies have investigated the efficacy of these attributes to the adoption of new IT.^[17] Moore and Benbasat^[17] used the attributes as a basis of developing an overall validated research instrument to measure the various perceptions of adopting an IT innovation. All attributes had fairly high alpha coefficients: relative advantage, 0.90; compatibility, 0.86; complexity (also called ease of use), 0.84; observability (also called result demonstrability), 0.79; and triability, 0.77. An alpha coefficient measures the squared correlation between observed scores and true scores. A high score means that the observed score is strongly correlated with the true score; which was the case with the Moore and Benbasat study.^[17] What follows is a discussion of each attribute in more detail.

Relative advantage

This construct captures both objective and perceived advantages of adopting the new IT. The literature shows that IT researchers have used different measures to assess the relative advantage of a new IT compared to the one it replaces. Six general interrelated and interdependent measures have been identified: *IT quality*, *information*

quality, *service quality*; *intention to use*, *actual usage*, *user satisfaction*, and *impact (including net benefits) to the individual and organization*.^[2,3] In 1992, DeLone and McLean^[3] reviewed 180 research studies on measures of information system success and drawing from the work of Shannon and Weaver^[68] came up with six measures: System Quality, Information Quality, Use, User Satisfaction, Individual Impact, and Organizational Impact. In a revised model in 2003, DeLone and McLean^[2] added Service Quality, Intention to Use, and generalized the Individual and Organizational impacts to one construct, namely, Net Benefits. We think these measures apply to IT adoption success as well. Given the multidimensional and interdependent nature of the IS success construct, the measures selected by researchers would depend on their research intentions. Fig. 3 shows the relationship between the various measures of the revised 2003 DeLone and McLean Model of Information Systems Success.^[2]

IT Quality. At the *IT quality* level, researchers have used “more engineering-oriented performance characteristics of the [IT] in question.”^[2] Specifically, research studies compared the new IT with the old one by focusing on resource and investment utilization,^[18] reliability,^[19] online response time,^[20] perceived usefulness,^[14,21] and accuracy.^[22] Overall, the studies found that any new IT that ranked higher in one or a combination of these factors had a higher chance of getting adopted compared to one that ranked lower. Other researchers have focused on measuring the relative advantage of the quality of the information generated by the new technology.

Information Quality. The perceived relative *quality of information* generated by a new IT in the form of reports is another determinant of successful IT adoption. Bailey and Pearson^[20] identified 39 IT-related items for measuring individual satisfaction with information quality. Out of the 39 items, the most important ones were accuracy, timeliness, reliability, completeness, relevance, precision, and currency. Other researchers have used other attributes of information quality such as uniqueness, conciseness, clarity and readability;^[23] and sufficiency, understandability, unbiasedness, quantitateness.^[24] Ahituv^[25] summarized the relative value of information into four main multiattribute utility category measures: *timeliness*, *content*, *format*, and *cost and benefit*. Timeliness includes a class of attributes related to the time factor in information update and retrieval. These time factors are: currency/recency, response time, and frequency. If a business transaction occurs in time t_0 , the related record may be updated later at time t_1 , and the user of this information may get a processed report at time t_2 ; the *currency of the data* presented to the user is measured by the difference $t_2 - t_0$. The *currency of the file* is measured by the difference $t_1 - t_0$ and the *response time* is measured by the

Fig. 3 DeLone and McLean IT success model.

Source: Adopted from DeLone and McLean.^[2]

difference $t_2 - t_1$. The *frequency of the reports* is measured by the number of times the user retrieves updated information for decision making. For example, if you have a bank account, monthly frequency statements may be sufficient. However, if you manage your own shares you may need daily or continuous updates of information from the stock exchanges.

Content attributes relate to the meaning of the information provided to the users. The attributes of content include: *accuracy*, *relevance*, *exhaustiveness*, *redundancy*, and *level of detail*. Accuracy refers to the integrity of the data used to produce reports. Relevance refers to the pertinence of the information to the decision at hand. Exhaustiveness refers to completeness or comprehensiveness of the information. Often, one can have relevant but incomplete information. Redundancy is the degree of repetitiveness of the information. Level of detail refers to the aggregation level of the data. The optimal level of aggregation is obtained when any extra detailed information does not improve the decision being made, and any more aggregation would worsen the decision.

Format attributes relate to the mode of presentation of the information. The attributes of format include: medium (hard copy, visual display, plotters, graphs, microfilm), layout (order of columns and rows, sequencing of detail and totals, etc.), and graphics design (colors, letter sets, fonts, etc.). Research studies on the format attributes have relied on the IT adopter's perceptions with respect to the medium, layout, and graphics design due to the problem of obtaining objective measurements. A laboratory study by Benbasat and Dexter^[26] found that whereas tabular reports led to better decision making, graphical reports led to

faster decision making by individuals under time pressure. However, they also found that reports with a combination of graphs and tables led to superior decision making when compared to tabular or graphical reports.^[26] Another study by Lim and Benbasat^[27] found that multimedia presentation using text, tables, video, and graphics reduced ambiguity, increased comprehension and accuracy of complex problem solving. These findings have been corroborated by studies on presenting spatial decision support information to managers when using geographical information systems.^[28]

Cost and benefit refers to the economic value of the new IT relative to the old one. The focus here is on reduction in fixed or variable costs, avoiding certain costs incurred while using the previous IT (e.g., overtime, stationery); profit enhancement through increased sales volume; and customer goodwill. The problem is that some benefits and costs are intangible and cannot easily be assigned monetary values. For example, it may be difficult to justify a new IT that could be used by a police 911 emergency services system to save lives. In this case how does one trade-off between the benefits of saving a life and the cost of the IT?

Overall, research studies that compared existing ITs to newer ones found that newer ITs that ranked higher on the timeliness, content, format and cost and benefit attributes; had a higher chance of getting adopted.

Service Quality. IT *service quality* is the gap between the IT adopter expected support and the actual support provided by a designated service provider, i.e., the IT vendor, the organization's Information Systems

Department, or other appointed third party. In formal settings, service level agreements (SLAs) could be made between the IT adopter and the service provider. An SLA is an adopter-driven formal written agreement that stipulates the level of service that will be provided.^[29] To evaluate an SLA, the IT adopter is asked to rate the level of service received for any number of itemized services using a rating scale, e.g., excellent (96–100%), above average (91–95%), satisfactory (86–90%), or unsatisfactory (below 86%). An unsatisfactory score may lead to non-adoption depending on the IT adopter's zone of tolerance. The zone of tolerance is the range of IT service an IT adopter would consider satisfactory.^[30] Service quality can also be measured using SERVQUAL, a 22-item instrument developed by market researchers for measuring service in general. The SERVQUAL measurement attributes are: *reliability*, *responsiveness*, *assurance*, *empathy*, and *tangibility*.^[31] Reliability is “the ability to perform the promised service dependably and accurately”; responsiveness is “the willingness to help customers and provide prompt service”; assurance is “the knowledge and courtesy of the [service] employees and their ability to inspire trust and confidence [in the IT adopters]”; and empathy is the ability to provide caring and individualized attention to the IT adopters.^[31] Tangibility is “the appearance of the physical facilities, equipment, and servicing personnel” including visual appeal, up-to-date service technology, and dress and neatness of the service personnel. Although some studies have praised the efficacy and robustness of the cognitive and psychometric properties of the SERVQUAL instrument,^[31–33] other studies provide criticism.^[34,35] Overall, such mixed results are common in most studies that solicit self-reported perceptual measures.

Behavioral Intention to Use, Actual Use, User Satisfaction. Given a relatively higher-quality new IT system that provides higher-quality information, and has high-quality service support; the other measures of successful IT adoption are: *behavioral intention to use*, *actual usage*, and *user satisfaction*. Fig. 3 shows that IT quality, information quality, and service quality have a joint impact on behavioral intention to use, actual use, and user satisfaction.

Behavioral intention to use/actual usage. Fig. 3 shows that there is a cyclical relationship between intention to use, actual usage, and user satisfaction. Behavioral intention to use is sometimes measured by a self-reported survey or by asking potential adopters their willingness to pay for the IT system.^[25] Some studies have measured actual usage by collecting data through hardware monitors, i.e., connect time,^[36] number of functions utilized,^[37] and actual charges for IT use.^[38] Other studies have measured IT use by questioning managers about their use of the IT.^[39–41] In either case, the success of an IT innovation will be measured by the degree to which the adopters rely on it, their feelings of ownership of the IT, and the degree

to which the IT becomes part and parcel of the standard operating procedures in the workplace.^[42] Moreover, in order to measure the actual use of a newly adopted IT, such use should be voluntary. We postpone the discussion of voluntariness to the section on type of innovation decision.

Each interaction with IT creates a certain level of *user satisfaction*. Other measures related to user satisfaction are *user enjoyment* and *user appreciation*. Increased satisfaction leads to repeated use of the IT, which in turn increases the user satisfaction level even further (hence the double arrows linking IT use to user satisfaction in Fig. 2). There is wide appeal among IT researchers to use this measure to evaluate success of new IT adoption. There is wide appeal to use of this measure to evaluate the success of a new IT adoption.^[2,20] Also, a number of research studies have found that user satisfaction from using a specific IT is related to their attitudes toward that IT.^[43,44] So, it is recommended that whenever user satisfaction is used as a measure of IT adoption, the users' attitudes should also be included in order to control for the biasing effects of the attitudes in the analysis—hence the arrow pointing to behavioral intention to use the IT innovation.

As shown in Fig. 2, behavioral intention to use, actual use, and user satisfaction have a joint *impact* on the *individual* or *organizations* using the IT innovation. It is generally accepted that information created by an IT is not beneficial until it is meaningful and useful to its user. Information technology benefits to the individual adopting the technology could include any of the following: a reduction in the average time to make a decision, increase in confidence in the decision made, increase in number of decisions made by a participant, increases in productivity, and increase in the number of reports requested by higher level managers. Researchers have used both quantitative and qualitative measures to evaluate the impact of IT on individual adopters. Quantitative measures include test scores, amount of performance improvement, time to make a decision, number of members participating in making a decision, and number of reports. Qualitative measures include: perceptions of improvement of decision making, perceived confidence in the decision, and the amount of money the adopters are willing to pay for the new IT.

Most managers are eventually concerned about the bottom line. It is therefore of interest to assess the *organizational* impact of new IT investments at the unit, department, or overall enterprise level. The recursive relationship on top of the “Impact of IT Adoption” box in Fig. 2 indicates that the aggregate of all individual impacts resulting from IT adoption in an organization contribute to the overall organizational impact. Several measures of IT organizational adoption impacts are available in the literature. They include overall: cost reduction,^[45,46] cost avoidance, increase in sales volume,^[47,48] reduction in overall operating expenses,^[49] and return on IT investment.^[50,51]

Current research has focused more on measuring the impact of IT on the organization structure,^[52] increases in customer switching costs, erecting barriers to new firm entry into the industry, product differentiation, and increasing organizational bargaining power with buyers or suppliers.^[46,53]

Summary. Relative advantage is “the degree to which an innovation is perceived as better than the one it replaces” as measured by the monetary gains, convenience, enjoyment, and satisfaction derived from its use. The greater the relative advantage, the higher the rate of adoption of the innovation. McLean and DeLone^[2] reviewed the IT literature and identified seven categories that can be used to assess the relative advantage of new IT investments, namely: IT quality, information quality, service quality, behavioral intention to use, actual usage, user satisfaction, and impact on the adopting individuals, organizations, extranets, industries, etc. Fig. 2 shows the relationship between the various measures.

Compatibility

One characteristic of IT is that it requires people to think, work, and behave differently. This emanates from the ability of IT to open organizational boundaries, integrate and coordinate work, speed up work, change the way work is done, provide faster feedback systems, and change perceptions of status and power.^[54] Not only should the various IT networks be compatible with each other, individuals should also adjust their work behavior to the new demands. Information technology can therefore place a significant amount of cognitive burden on users—who may not only be unsure about their job situation but also may have to invest in education and training in new skills. *Compatibility* is the degree to which the new IT is perceived as being consistent with the existing values, past experiences of adopters, and existing IT applications and networks. In Fig. 2, compatibility belongs to the behavioral intention to use, actual usage, and satisfaction category. Whenever there is lack of compatibility, passive or active resistance may occur.^[55]

It is therefore recommended that users be involved in IT acquisition and implementation decisions. As recommended by Osterman:^[54]

Beyond investing in people early, through education, training in new skills and so forth, it turns out to be helpful for the organization to develop flexible human resource policies that enable and encourage the organization to capitalize on the new IT. Employees at all levels are more inclined to experiment with new ways of working if they know their standing in the organization will not be affected by their learning process. (p. 220)

Several studies have identified compatibility as an important factor in IT adoption. One classical study is the one

reported by Markus.^[55] In the study by Moore and Benbasat^[17] a factor analysis grouped compatibility with relative advantage.

Complexity

Complexity is a relative measure of perceived cognitive burden imposed by the new IT. In Fig. 2, complexity belongs to the IT quality category. Measures of complexity include ease of use,^[14,56,57] ease of learning,^[58] and enjoyment.^[59] The more user-friendly a particular innovation is, the greater it's potential for adoption.

Triability

The ability to try out a new IT before integrating it into the routine activities and standard operating procedures of the workplace is an important measure of IT adoption. Triability affords individuals and organizations the opportunity to investigate the relative advantages, compatibility, complexity, and observability of the new IT. The study by Moore and Benbasat^[17] found that although triability had significantly less weight than other factors in an organizational context, it should be of great concern for organizations that would adopt IT at their own risk.

Observability

Observability includes the ability to demonstrate the results (benefits and costs) of using the IT to potential users, as well as making the results visible to others within and outside the organization. Users are more likely to use a new IT if they feel that using the IT will bring higher approval and recognition from management and colleagues. In Fig. 2, observability could belong to the user satisfaction category.

Summary. A new IT that is perceived to be relatively useful, compatible, easy to learn and use, has observable results, and can be used on a pilot basis will most likely be adopted than the one that is lacking in any or all of these attributes.

Type of Innovation Decision

There are three types of innovation decisions: voluntary, authoritative, and collective. Innovations requiring the adopter's voluntary decision to adopt are generally more rapidly adopted than innovations that are mandated by an organization or other external pressures.^[1] Voluntariness of use is the degree to which the use of the IT is perceived as being voluntary or of free will. In Fig. 2, the type of innovation decision belongs to the behavioral intention to use, actual use, and satisfaction category.

At the individual level, management may mandate (authoritatively) the use a specific IT, or may provide incentives for those who use the specific IT. Sometimes

management may even enact policies that discourage the use of a specific IT. The decision to adopt may also be made by a few IT champions in the organization and then imposed on the rest of the business unit or department.

At the organizational level, an organization may be forced to adopt specific ITs in order to survive competition in their industry. In this case, IT becomes the cost of doing business. For example, a new bank may adopt ATM machine technology as the cost of doing business, irrespective of whether the benefit of implementing ATM technology has been proven in the specific area of operation. These circumstances deny the adopter the freedom of choosing to reject the IT.

According to Ajzen and Fishbein,^[60] it is often not actual voluntariness that influences behavior, but rather, the perception of voluntariness. This means the rate of adoption will be increased if the people championing the adoption of the IT (change agents) can successfully make the adopters believe that they are the ones who are choosing to adopt. To accomplish this, change agents must understand the dynamics of change. Lewin^[61] and Schein^[62] proposed a three-stage model for managing change (see Fig. 4).

Unfreezing is a process of removing old habits and creating a climate receptive to change. Moving is the process of learning new work methods, behaviors, and systems. Refreezing is the process of reinforcing the new changes so that the new work processes and behavior are accepted as part and parcel of job. When a new IT is introduced, IT professionals become the agents for change. An understanding of the dynamics of change can help change agents understand how to make IT implementation more successful.

The number of people involved in decision making is another factor that may affect successful IT adoption. Rogers^[1] observed that the more people or institutions are involved in making an innovation adoption decision, the slower the rate of adoption. Few studies in the IT adoption literature have focused on this aspect. One notable study is the one by Keen.^[63] He noted that increasing the number of people involved in the IT adoption decision could be a tactic to prevent implementation success. He called this phenomenon counterimplementation.

Communication Channels

The communication channels used to spread information about the relative advantages, compatibility, complexity, triability, and observability of the new IT can also influence the rate of adoption. Mass media is recommended when the

Fig. 4 The Kurt Lewin and Edgar Schein model.

new IT is relatively simple to use. For example in 2007, Microsoft spent more than \$500 million to advertise their flagship Vista operating system because they believed the Vista interface was relatively intuitive to use. Interpersonal contacts with change agents are recommended when the new IT is perceived by potential adopters to be complex. For example, we observed that computer-assisted software engineering (CASE) tools such as AutoCAD are mainly marketed via interpersonal contacts between vendors and potential professional users in academia or industry.

Nature of the Social System

This includes the norms of the organization where the new IT is being adopted and the existence of interpersonal network influences on potential but skeptical adopters. In an organization receptive to new IT ideas, opinion leaders play a significant role in providing innovation-evaluation information critical to decreasing uncertainty about the new IT. Opinion leaders are those adopters who act as role models in influencing others opinions about innovations. As will be discussed later, these people belong to the early adopters' category.

Extent of Change Agents' Promotional Efforts

The rate of adoption is also influenced by the extent of the promotional efforts of the change agents. The more opinion leaders the change agent can convert, the greater the rate of adoption. The rate of adoption and the extent of the change agents' efforts may not be direct or linear; however, Rogers^[1] observed that the rate of adoption is greatest when opinion leaders adopt, and continues to grow with little promotion by change agents after a critical mass of adopters has been established. A critical mass is defined as the point at which enough adopters have accepted the new IT to cause the perceived cost-benefit of adoption to shift from negative to positive.^[55]

Summary

Left on their own volition, not all individuals, organizations, or nations are receptive to IT adoption; there is considerable skepticism about the real benefits of IT adoption. The rate of adoption of an innovation depends on the perceived attributes of the innovation, the type of innovation decision, communication channels used to advertise the technology, nature of the social system where the IT is implemented, and extent of the promotional efforts of change agents. Often, it is not the actual voluntariness of the decision to adopt a new IT that influences behavior, but rather, the perception of voluntariness. Change agents who understand the dynamics of change can play a role in influencing successful IT adoption. The stages through which a technological innovation passes are

- Knowledge (exposure to its existence and understanding its functions)
- Persuasion (the forming of favorable attitudes toward using it)
- Decision (behavioral intention to invest, experiment, learn and commit to its adaptation)
- Implementation (putting it to use)
- Confirmation (reinforcement based on positive net benefits received as a result of adopting it)

PART 2: RATE OF IT ADOPTION CATEGORIES

In part 1, we discussed the important elements of successful IT adoption. We noted that despite the overwhelming opportunities offered by IT, however, not all individuals or organizations may implement a new IT at the same rate. Even when the adoption decision is mandated (authoritatively or collectively), users may not implement the full features of the new IT at the same rate.

One way to describe the rate of IT adoption or consumption is to use the “S-Curve of Adoption and Normality” developed by Rogers.^[1] Although some research has found only weak support for the S-Curve,^[64] many studies have supported its applicability especially in the early days of the introduction of a new IT.^[1,65,66] The S-Curve is shown in Fig. 5. According to the S-Curve, the first 2.5% (i.e., minus 2 standard deviations) of individuals or organizations to adopt IT are called the innovators. The next 13.5% (i.e., between the mean minus 1 standard deviation and the mean minus 2 standard deviations) are called the early adopters. The next 34% (between the mean and the mean minus 1 standard deviation), are called the early majority. The next 34% (between the mean and the mean plus 1 standard deviation) are the late adopters, and the remaining 16% (above the mean plus 1 standard deviation) are called the laggards.

Fig. 5 The S-Curve of adoption and normality.

Individuals

Innovators are the first 2.5% of IT users. They include venturesome or cosmopolitan individuals who have enough resources to acquire and experiment with new IT or can have their organizations buy the technology for them. The value of IT to innovators is the potential return they may get for being the first to try a potentially beneficial technology. People working in beta and alpha test sites for new software applications belong to this category. Innovators command a certain amount of social prestige and peer respect for being at the cutting edge of IT. Observability and triability are the two main attributes at play here.

Early adopters are the next 13.5% of people to perceive the relative advantage, compatibility, and observability of a new IT and are willing to pioneer its use. Early adopters are valued as change agents, and as such, have high subjective norms.^[60] Subjective norm is a social influence term that refers to the importance the person attaches to opinions of referent others. “The early adopter knows that [in order] to continue to earn [the] self respect of colleagues and to maintain a central position in the communication networks of the IT system, he or she must make judicious innovation decisions...”.^[1] As such, early adopters are motivated by the social influence and respect they obtain from their peers.

Early majority is a group of individuals who adopt IT because it has been proven to work. Comprising 34% of the IT adopter category, the early majority are the first most numerous group to implement the new IT. As such they bring in a “critical mass” of IT users. This group interacts with the early adopters to get guidance on how to use the new IT. Moreover, they provide interpersonal networks to the late majority.

Late majority comprise of skeptical individuals who adopt IT for fear of losing their jobs or due to peer pressure. Like the early majority, they comprise 34% of the new IT adopter categories. Additionally, individuals in this category may not have enough resources to spend on IT and hence have to rationalize any IT expenditure they consider risky or uncertain.

Laggards are the remaining 16% of the adopters who may fear computers, have negative attitudes toward computers, or have the fear of using poorly designed systems. Laggards tend to be suspicious of new IT and change agents. They want to be sure about the costs and benefits of adopting the new IT before accepting it. Similar to the late majority, individuals in this category may not have enough resources to spend on IT.

Summary

Individuals can be innovators, early adopters, early majority, late majority, or laggard depending on the impact of the rate of adoption variables on them. There are both

intrinsic and extrinsic factors influencing how adopters perceive the rate of adoption variables. Innovators value IT for the potential returns that may accrue by being the first to try a potentially beneficial technology. They hope that by the time other groups catch on, they will be high up on the learning curve. Early adopters are motivated by the respect they obtain from their peers and their value as change agents. The early majority are risk averse individuals who join the IT bandwagon only when it has been proven to work. The late majority are skeptical individuals who adopt IT as the last resort. Finally, the laggards adopt new IT only when they can ascertain all the benefits and costs.

Organizations

Innovators are the first 2.5% of organizations which adopt a specific IT. Such organizations either have enough resources to acquire and experiment with new IT or have an influential Management Information Systems (MIS) department manager who has a secure budget for new IT. The value of IT to innovator organizations is the competitive advantage that may accrue for being the first to try a potentially beneficial technology.

Early adopters are the next 13.5% of organizations to perceive the relative advantage, compatibility, and observability of a new IT early and are willing to pioneer its use. Most organizations in volatile industries, e.g., computer hardware, computer software, telecommunications, and entertainment are forced to become early adopters of new IT. Volatile industries are ones characterized by cut throat competition and uncertainty. For example, Microsoft's late move into the Internet search engine market cost the company significant competitive advantage, albeit temporarily. Early adopters develop ways to use IT to lock in customers and lock out competitors early, and as such, tend to maintain their market share, which in turn, increases their chances for long-term survival and profitability. These early adopters are motivated by the customer loyalty they obtain due to their innovative efforts to provide higher-quality products and service.

Early majority is a group of organizations who adopt IT because it has been proven to work. Comprising 34% of the IT adopter category, the early majority are the first most numerous group of organizations to implement the new IT. As such they form part of a "critical mass" of IT using organizations. This group of organizations sometimes assigns specific individuals the role of reading the literature on the experiences of the early adopting organizations in order to get guidance on how to use the new IT. Other organizations employ people from the early adopting organizations so that they can benefit from their experiences. In other instances, organizations may acquire or enter into strategic alliances with early adopting organizations in order to learn from them. In other cases, organizations have formed a separate organizational unit

called the "emerging technology group" to oversee IT adoption into the organization.

Late majority are skeptical organizations who adopt IT for fear of being swept away by the competition. Like the early majority, they comprise 34% of the new IT adopter categories. Organizations in this category may not have enough resources to spend on IT, and hence have to rationalize the IT-related expenditure they consider risky or uncertain.

Laggards are the remaining 16% of the adopting organizations who may believe "if ain't broke, why fix it?" Laggard organizations tend to be suspicious of new IT and the hype that surrounds new ITs. They want to be sure about the costs and benefits of adopting the new IT before implementing it. Similar to the late majority, organizations in this category may not have enough resources to spend on IT. They also want tried and proven technology.

Summary

Organizations can be innovators, early adopters, early majority, late majority, or laggard depending on their mission, culture, the nature of the industry they are in, their structure, and the impact of the rate of adoption variables on the long-term profitability and survival of the organization. The decision to adopt or not to adopt is mainly driven by demands from the internal and external environment of the organization. For example, organizations with a culture that emphasizes "internal control," "creativity," and "individual autonomy" are more likely to adopt new IT than the ones that emphasize "external controls," "conformity," and "hierarchies."^[67]

Innovators value IT for the potential returns that may accrue by being the first to try a potentially beneficial technology. Early adopters are motivated by the customer loyalty they create by providing better products and superior service. Such organizations hope that by the time other organizations catch on, it would be difficult for them to tap into their market share. The early majority are risk adverse organizations which are in relatively stable operating environments. Most public sector organizations fall into this category. The late majority are skeptical organizations which adopt IT as the last resort. Finally, the laggards are would adopt a new IT only when they can establish all the benefits and costs of the new IT.

CONCLUSION

We conclude by suggesting that since the proliferation of newer and more powerful ITs is apt to continue unabated for many years to come, there is a real need for individuals and organizations to devise new ways of identifying, learning, and implementing new technologies. One way to do this is to have a clear understanding of the factors that influence successful adoption of IT. Specific factors

that may influence IT adoption in particular industries, national states, or societies are beyond the scope of this entry. This entry used the variables that affect the rate of adoption of IT innovations (see the section "Part 1: Adoption of IT innovations"), the categories of successful IT adoption (see the section "Part 2: Rate of IT Adoption Categories"), and the S-Curve (see the section "Part 1: Adoption of IT innovations") to provide a general overview of existing literature on new IT adoption by individuals and organizations. The variables that influence successful adoption and the categories of successful IT adoption are multidimensional and interrelated. For example, one cannot discuss the relative advantage of a specific IT without considering the IT quality, information quality, usage of the information provided by the IT, user satisfaction, and benefits accruing to the individual and organizational adopters. Use of the S-Curve will allow individuals and organizations to position themselves with respect to where they fit in their rate of IT adoption. It seems individual life long learning, and organizational learning are the indispensable characteristics of the very survival of an increasingly IT dependent society: One caveat though: "... management can promote the acquisition of skills by creating a climate supporting continuous learning in general and by encouraging experimentation with IT tools in particular..."^[68] (p. 275).

Information Technology Literacy

James W. Marcum

Fairleigh Dickinson University, Teaneck, New Jersey, U.S.A.

Abstract

Information technology literacy is a broad, many-dimensional description of the skills and knowledge needed for effective participation in business and education in the twenty-first century. First considered to be generic, those capabilities are now understood to be contextual, social, determined by the specific situation, be it workplace, academic, or social. This becomes clear when the term is compared to information literacy (knowing when information is needed, search strategy development, accessing and managing the information, and using it legally and ethically to meet the need). Information literacy (IL) is extensively explored and discussed in a vast literature. There remains considerable disagreement about what it is and how it should be taught and assessed; yet IL is relatively simple compared to the less developed concept of IT literacy. Information technology literacy involves using the tools of information technology (hardware, software, networks) as well as the data and information (as with IL), as well as working in a specific context (which might be professional, social, industrial, or academic). Workplace, social, behavioral, and cognitive issues become, therefore, part of the complexities in play. Furthermore, complexity accelerates as new media, new communication technologies, and new collaborative capabilities combine to create a dynamic information universe of participation and interactivity. This emergent reality changes the way people learn and the very nature of knowledge. Librarianship, scholarship, research, business, and the professions are all being reformulated in the process of adapting to these new conditions. Information technology (IT) literacy provides a useful concept for tracing, exploring, and better understanding this world-changing phenomenon.

INTRODUCTION

Information technology literacy is a significant, if not fully delineated, concept of the knowledge and skills needed for effective participation in the age of information, knowledge, learning, and networks that characterize the new millennium. The term offers approaches to needed knowledge and skills and guidelines to support the development of these competencies by students and learners. Information technology (IT) literacy resides among, and overlaps in some measure, other definitions including computer literacy, visual literacy, media literacy, digital literacy, multiliteracies, information literacy, information competence, fluency with information technology, and information-communication technology literacy. In this brief discussion a broad-gauged perspective is taken of the issues, suggesting that IT literacy does not require a major campaign to distinguish it from the other, closely related definitions, but that defining and discussing IT literacy provides the opportunity to trace, develop, and illustrate the relationships and manifestations of the roles and effective uses of technology in society, the workplace, and in education. The discussion loops back toward a conclusion that IT literacy—or perhaps “information and technology literacy”—is a useful descriptor for a range of theories and

practices that come together to lead to a better understanding of a complex situation.

Information technology literacy means being “information literate” (able to find, access, and use information to solve the need of the seeker) as well as “technology literate,” sufficiently skilled for competent utilization of a networked, interactive, multimedia environment.^[1] An outline history of the topic reveals major shifts in technology and its impact in recent decades and the resulting adaptations as professions exchange the lead position in discussing the significance of those changes.

With the rise of the personal computer (PC) in the 1980s, and the rapid expansion in the number of people using the tool, the need for “computer literacy” became apparent and IT specialists and information scientists took the lead in defining and refining the term. The PC was difficult to use—before Apple and Windows software and World Wide Web (hereafter simply Web) search engines rendered it more intuitive—and “technical” people led the way in exploring how to train others to utilize the new “machines.”

In the 1990s, with the growth of the Internet, intuitive and graphic interfaces, and the number of “user friendly” databases of information available, information literacy became the focus of the discussion and librarians,

particularly academic librarians, moved center stage as the champions of preparing a wider public to use the new tools, resources, and technologies made available by the Internet. The work soon expanded to encompass a much broader “digital” world of communications and visual/multiple media resources.^[2] As we entered a new millennium, a variety of substantive definitions of information literacy demanded consideration and competed for influence. A federal government initiative proposed Fluency with Information Technology (FIT) as the appropriate metaphor;^[3] the Educational Testing Service proposed information and communication technologies (ICT) literacy as the preferred concept;^[4] and academic librarians broadened their concerns to encompass “competencies” that could be measured to assure appropriate “learning outcomes.”^[5] The ground soon shifted toward a broader perspective, leading to serious consideration of the need for definitions and a model for IT literacy. Shapiro and Hughes^[6] suggested, in a much cited article, that information literacy (IL) could be a stand-alone liberal art, that both the tools of IT and an ability to perceive emerging technologies were important elements of the model.

Getting more specific, Brandt proposed in his 2001 article^[1] the need to think in terms of a broader “computer literacy” and a bridge to IL. A few years later Brandt and colleagues returned to the issue and proposed merging IT literacy with IL as the more comprehensive and proper approach.^[7] By this time, roughly 2005, focus shifted away from information literacy back toward the technology side of the IT literacy equation. There are several features of this shift. The broader view was already becoming accepted. The National Research Council reported in 2002^[8] that IT was clearly impacting teaching and research, compelling new collaboration and restructuring intellectual disciplines, pointing to a clear need for faculty and many others to “reskill.”

During the early years of the new century, communications and education professionals—and practitioners—actively engaged in the discussion, arguing for the crucial importance of media literacy, instructional design, and related concerns. The dialogue continues. While different descriptors are preferred by various proponents of IT literacy, there is a general consensus regarding the critical importance of literacy—or fluency or competence—for effective participation in the classrooms, offices, and workplaces of the day. Each of the perspectives adds something to the larger picture, and this overview will endeavor to be inclusive.

STAGES AND LIMITATIONS OF LITERACY

Tracking the evolution of literacy and its segue into considerations of fluency and competence is a useful path for exploring the power of technology and networks to change, nay revolutionize, not only how we search for

and share information, but how we learn and carry on business, polity, and entertainment. The varieties of literacy “in use” provide a connecting theme for this many-faceted development.

Basic Literacy

Literacy in the broadest sense is a process that is valued by society. The term is popularly understood, however, to mean simply the ability to read and write. By implication, basic communication skills are included. This is the social dimension to literacy in that people need others to help them learn to read and write. Literacy cannot be self-generated, as a rule, because meanings must be social and not just personal. More is involved than reading, however. Literacy is a human phenomenon, grounded in a social context. Meaning comes from interpretation and influence, both of which are social. A substantial “politics” swirls around the issue, seen by some as a means by which a society maintains control, sets priorities, and shapes cultures.^[9] Bilingual people and individuals with advanced literacies enjoy special advantage; they can communicate at another level. A consideration of literacy cannot dwell long at the level of learning how to read.

Advanced Literacies

A second spoken language, a symbolic language (such as mathematics or a programming algorithm), and various other skills indicate advanced capabilities. Basic information tool literacies, such as desktop computer literacy, visual literacy, or new media skills are alternative abilities signaling advanced literacy. Navigating the Web and participating in wikis or instant messaging systems or social gaming are necessary skills in many workplaces. Communication skills are more advanced at this level, moving beyond basic signaling to greater engagement, where information is shared and can lead to improved coordination among people and between organizations. These literacies quickly become more specialized, often requiring additional media tools or different perspectives. Literacy becomes a process of making meaning out of confusion; advanced literacy involves dealing with the complexities of learning, text, and context leading to improved understanding and dynamic relationships.^[10] Kuhlthau^[11] puts it succinctly: literacy is the ability to construct one’s own meaning from an information rich environment.

At this point, technological literacy has moved well beyond computer skills, entering the realm of working effectively in a given context which, today, is likely to have a moderate to high level of electronic devices as basic tools. Achieving technological literacy broadly across society is a great challenge and carries an enormous cost that will require involvement of the state, education, and the corporate sector.

Visual and Media Literacies

In recent decades, the impact of broadcast media and the Web requires a greater literacy, or better understanding, of how visual images are created and used. Reliance on the image, especially the moving image, in communication and the easy manipulation (morphing) of these images requires higher levels of technological competence and different ways of thinking or, more specifically, new cognitive skills.^[12] What we “see” is in good part actively “constructed” by the individual mind (amidst social influences of course), not passively received through vision.^[13] The fact that visual communication can bring together codified (linguistic) and uncoded (tacit or experiential) knowledge gives the technology enormous power. For example, hand-drawn sketches and lists of words and ideas are popular for planning and brainstorming sessions. Heretofore separate genres (text, graphics, audio, and video) converge into digital communication capabilities: symbols, images, and words are now mixed, replicated, and widely disseminated on Web pages, advertisements, and presentations.^[13]

In the emerging information-learning culture a reversal is well underway: where the word long held sway and the image augmented, increasingly the image now dominates and the verbal augments. Today visual language is proposed as a way of integrating words, images, and shapes into a new language for communication and understanding. This “visual language” makes learning accessible to many more people.^[2,14,15] Visual language warrants additional investigation and demonstration; for one thing it offers an escape route out of the gridlock of print vs. digital media arguments.

Media literacy is central to modern communication studies. It involves the ability to access, analyze, evaluate, and communicate messages in a variety of formats. Digital media literacy utilizes information digitization to perceive and present a distributed, interactive, malleable world. This is not an extension of TV, but the antithesis of it; the viewer—particularly the younger generation—is taking charge of their own information. Labeled “new media literacy,” new image production tools allow *many* more people to create media and join in the great “conversation” facilitated by the Internet even if only a tiny percentage actually gain attention and achieve influence.^[16]

Some of these literacies are narrow, of interest only to select disciplines. Nevertheless, a holistic concept of literacy permits escape from many limitations and allows entry into more demanding realms.

Literacy 2.0: Social and Workplace Literacies

At this point the discussion moves into the more complex dimension that can be called “Literacy 2.0,” the ability to use information in whatever format to interact with others to solve problems and create new knowledge. In a sense,

solving a new problem, even in a narrow field or context, can be considered the creation of new knowledge.

Literacy 2.0 or workplace IT literacies is a shorthand label for the increasing skills required in more and more lines of employment. These skills are contextual, varying with the social, professional, and intellectual practices of a given workplace. In addition to information literacy, this capacity builds competence in contexts that change frequently. Neither basic literacy skills nor higher order thinking skills are sufficient. Literacy as traditionally constructed rarely is informed by actual observations of work.^[17] Workplace literacy involves participation and is something very different from traditional training or education.^[18] In the varied and complex world of the workplace, different terminologies are used—such as fluency with IT—and other methods, such as relying on “masters” as mentors.^[19] Additionally, other articulated literacies are valuable. For example, “learning literacy” requires learning one’s own “identity” and learning style as well as learning skills.^[20] Rosen^[21] defines “social literacy” as the skills required for leadership; these include inspiring others to excellence, listening and communicating effectively, promoting common goals and values, and transforming conflict into creative action.

Socio-technical practice warrants mention. Tuominen and colleagues^[22] emphasize that IL and IT literacy cannot remain detached and generic practices but are situated, in a given workplace, context, a community of practice, or within a disciplinary, epistemic methodology. While the Tuominen article is ostensibly about IL, its breadth of consideration renders it useful for this discussion.

Multiliteracies

The case for multiliteracies provides a culmination for the literacy discussion. A wide-ranging effort of a group of international experts in learning and language has created a pedagogy of social and multimodal learning. They bring the meaning of literacy to a new level of importance by including such work life issues as competitiveness, coping with diversity, and collaboration. Information design is essential and interface icons are important as a meta-language to allow access for many more people.^[23]

An additional note on the term, literacy: The label of illiteracy clearly implies that a fundamental skill is lacking. In situations where people are engaged in learning and willing to acknowledge their limitations, illiteracy is not deemed insulting or belittling. Indeed, each of us has our illiteracies, domains where general information and skills are lacking, and where basic instruction is appropriate. But common sense requires that additional levels, beyond the basics, provide part of the scheme for the ongoing, dynamic world of interactive communication and learning that has become central for our time. That is why a literacy-competency-expertise continuum is useful as a design for framing the process of continuous learning.

There is no simple conclusion to this discussion. We live amidst increasing complexity and the list of proposed literacies allows the seeker to select the model that best fits their situation and context. Information technology literacy will work for many of these situations, but no single definition will be found satisfying to all.

THE NECESSITY OF COMPETENCE

Today's workplace requires more than either special skills or general knowledge; it also requires competence involving personal characteristics and behaviors that can be measured or recorded. Such competence encompasses cognitive knowledge, functional experience, and interpersonal, social skills and is a recurring concern in higher education and for human resource training and development. Brief consideration is necessary to complete this overview of IT literacy.

The issue is not new; a half-century ago a proposed standard of biological factors including growth potential, maturity, and behaviors defined competence as the functional ability of humans to exercise personal independence and social responsibility.^[24] Before the rise of the PC, Reisman^[25] outlined society's need for competence and higher education's poor record in developing those skills among the young. More recent versions of the need for competence stress the importance of character and emotions, both managing one's own emotions and coping with the emotional behavior of others.^[26,27]

At present, there are several approaches to competence, creating some confusion. One approach relies on behaviors, including cognitive behaviors (thinking; learning; and information processing); affective behaviors (managing and using emotions and feelings productively); conative behaviors (persistence and determination); and habits and experience. Competence requires participation in the process, whatever the work or assignment.^[28] A second approach to competence stresses skills, including managing self (adapting, dealing with change); communicating with diverse people and groups; managing people and tasks (coordinating resources and people); mobilizing innovation and change; and taking initiative.^[29] Sveiby provides a concise overview, delineating five elements: knowledge of the explicit domain ("knowing what"); appropriate skills ("knowing how"); sufficient experience in the domain; exhibiting appropriate value judgment ("knowing why"); and having a social network ("knowing who") in the domain. One cannot be an effective professional, or worker in most fields, without knowing and carrying on dialogue with others in the profession, field, or practice.^[30] To repeat for emphasis, a combination of behavior, skills, and knowledge is needed to demonstrate the broad capabilities that make up competence, or an overarching meta-competence.^[31]

Information Technology Competence

The ability to use IT in the workplace is obviously essential today.^[18] Yet that is insufficient. A more advanced level of skills, such as fluency or expertise, is required more and more frequently as businesses and organizations adapt to the information age. A federal government expression of these advanced skills is Fluency with Information Technology (FIT). Fluency is defined as higher levels of competence. Fluency with Information Technology goes beyond skills (which are quickly obsolete) and includes problem-solving capabilities.^[3] New information and communication technologies enable a new era of information and knowledge grounded in interactivity. Not media as signal, but media as action-perception cycle is the emerging reality.^[32] Individuals working alone cannot be expected to master all these technologies. Teams or workgroups are required to encompass the variety of skills and knowledge needed to deal with the complexities of today's problems with the extensive range of tools and resources available.

Social competence

Today competent people must be able to collaborate with others of diverse backgrounds. The sharing of work between genders and across ethnic lines and national and cultural frontiers is essential. New standards of people skills, supervisory skills, and management skills are vital. Teams and communities of practice are frequently required for organizations to adapt to meet the challenges they face. At this level, communication becomes interactive and participatory; top-down signals are often dysfunctional. Organizational change is becoming more common, requiring cross-boundary partnerships, research, and innovation. These techniques require social competence.^[33] Today's places of work and learning are more often participatory and interactive in nature.

Socio-technological information (cyber) competence

What would address all of the necessary elements of information-related competencies required today? One possibility is social-technological information competence, or cyber-competence for a shorthand definition. Cyber-competence consists of the converging technology-based interactive skills and practices required to find and utilize information in multiple formats and varied contexts to encourage knowledge sharing, foster knowledge creation, and enhance organizational effectiveness in a competitive global and networked environment. Elements of "cyber competence" include Internet research and communication; visual and media literacy; digitization, visualization, and presentation; interactive communication and networking; self-knowledge and reflection; and action research skills. Competent people will be able to find needed information, utilize and manipulate it for new purposes, know

how to use new tools, learn new skills, and assess their own progress and development.

To focus for a moment on the library-centered world, it is appropriate to insert here that there is growing attention to and consideration of the notion of “information competence.” Information competence is included in the general discussion of information literacy to demonstrate that the appropriate level of literacy has been accomplished.^[5] To illustrate, projects at UCLA and the California State University system have demonstrated, experimented with, and evaluated how information competence might best be implemented on the university campus.^[34,35] A review of these efforts suggests, however—regardless of the value of the endeavor—that the underlying assumption regards literacy and competence as essentially equivalent, a continuum, whereas others emphasize their differences.

More technology-minded discussants might argue that “instructional systems design” (ISD) is the path to follow. On this topic the work of the American Society for Training and Development becomes significant. Instructional systems design is work-context focused and takes a systematic, logical approach to the skills needed with tracking and assessment built in. The limitation of this model is that its intent is the *transfer* of information and/or knowledge, existing knowledge, rather than the creation of new knowledge.

It is important to realize that the emphasis on competence requires a major shift beyond the data–information–knowledge transfer continuum to a more dynamic learning domain—expressed in the term Internet 2.0 or Library 2.0—demanding more comprehensive capabilities. More content knowledge does not help; it must be tested in the real world of the workplace, or the lab, or other social–economic–political domain.

Can Competence Be Taught?

Functional effectiveness in today’s workplace requires social skills and emotional stability as a supplement to IT literacy; competence requires experience in practice. Competent behavior rarely depends entirely on formal knowledge.^[36] Individual brilliance is not always highly prized in work situations unless it produces unique solutions to problem situations. “Learning” must be broadened to mean learning to make one’s own observations, to lead, to work with others, to clarify values, to correct actions, to understand how organizations work and how to influence them. A quick look at incompetence helps define competence: Incompetence can include deficits in skills or knowledge, but the list of personal factors is longer, including unprofessional behaviors or attitudes, difficult personality traits, lack of motivation, unsafe activities, or poor communication skills.^[37]

Some efforts skip over educational standards. A U.S. Department of Education conference on “Competence without Credentials”^[38] considered whether new Internet-based

instruction could replace traditional credentials and certificates, apparently on the assumption that assessed workplace performance and computer-based learning were inadequate for the social, interpersonal, and collaborative dimensions of effective work. The assumption in this essay is, however, that enhancing student competence increasingly will be an important challenge for the future of education. While reading and writing are basic skills that can be transferred to many situations, workplace competency often is highly specialized, grounded in the specific work context. It cannot be taught; it must be learned and demonstrated “on the job.”

Beyond Competence to Expertise

If competence is the goal for workplace effectiveness, it ultimately is insufficient. In a technology-driven world, today’s competence can vanish with a new software release. It is expertise that is the goal at critical times in the information-gathering, decision-making human development process. Whether we face eye surgery or planning for retirement, there are circumstances where competence is not the ideal. We require expertise, someone who has mastered the rules and understands them so completely that they can cross the lines when circumstances demand. According to one report, it is the development of relevant knowledge structures and the ability to monitor their own thinking processes and adapt them as necessary that distinguishes the work of experts.^[39] It is this level of expertise that is the ultimate goal of the learning–literacy–competence continuum. Expertise requires capabilities of learning, growth, and adaptation to changes in the “ecology” of the context.^[40] This point takes us, however, beyond the scope of this discussion.

A BRIEF GLOBAL PERSPECTIVE

We can generalize with confidence that IL and IT literacy are of greater concern in democratic societies than in less developed countries. Training is widespread in Europe, where searches for writings on “digital literacy” uncover more activity than “IT literacy” searches. There is great variety in skill levels and the intensity of library activities promoting the capability within the EU, as might be expected with recent incorporation of former Soviet-dominated areas. A British survey of national policies suggests that the global trend is clearly toward greater openness as an encouragement to innovation, e-commerce, and e-government and growing recognition that information is now a key driver in building social and economic prosperity. A widespread pattern of specific programs to build broad citizen activity and learning has not yet emerged.^[41] The assumption that providing access to computers and the Internet is sufficient is commonly held in many parts of the world.

Henri and Asselin^[42] work from a similar premise to present widespread activity on the part of the library professions to promote IL and IT literacies in the schools in many areas of the world. The articles they present suggest emergent themes including “new learning,” new literacies and multiliteracies, and the potential role that teachers and librarians play in creating information literate schools and communities. This work does not focus on IT literacy but many of the points are relevant. The difficulties in distinguishing IL and IT literacy mentioned in the introduction of this discussion once again merit noting.

Information Culture Literacy

When focus shifts beyond the Western democracies, a different perspective comes into view. Global library leadership, associated with IFLA (International Federation of Library Associations) is working closely with UNESCO to promote global access to information and learning under a flag of Information for All Programme (IFAP).^[43] This initiative has produced additional studies and reports making a case regarding the need to address the challenges of a comprehensive information culture. Not an information society, but information culture, requiring reading, gathering, and managing information, and ongoing learning and knowledge improvement. This dynamic process encompasses upgrading knowledge and human intellect, designing and utilizing diverse media for communication, improving understanding, and expanding the uses and socialization of information throughout human activity.^[44] This perspective reveals that individuals have personal information cultures, varying widely in their world outlook and system of knowledge, seeking information narrowly or widely, competently or carelessly, thoughtfully and critically or mindlessly and without reflection. Their engagement in or neglect of the process shapes their mindset, determining whether they are open or closed-minded, learning and growing, or stagnant.^[45]

The UNESCO program, seeing information and knowledge as a global public good and basic human right for improving health, advancing education, furthering creativity, and preserving diversity and the human heritage, adds enormous value to the work of IL and IT literacy advancement. The importance of reading is stressed, compared with its declining status in this country. We find that the United States is not among the top dozen countries in achieving high levels of reading competence in its students.^[45] UNESCO positions reading for pleasure and learning as a vital task for libraries, museums, and information institutions; this is a sobering counter-trend to the technology-focused IT literacy movement.

CURRENT AND FUTURE ISSUES

Several issues and debates not yet addressed are important to the topic. They include the need to rethink the

relationship of IT literacy and information literacy, the difficulties of assessing IT literacy; the new focus on learning and innovation, the posture libraries should consider for addressing these challenges, the changing nature of knowledge, and the consequences of growing complexity in society triggered by networks and connectivism. Brief discussions of these issues follow.

Issues with Terminology

Sharkey and Brandt^[7] combine earlier arguments to make the case that both information literacy and IT literacy are required capabilities for our day. Assessment of outcomes must be part of the process. None of the pieces of the larger picture suffice. The user's access and use of the information to good effect may require an electronic presentation, or a range of papers and presentations comprising an electronic portfolio of the work done and progress achieved. Work remains to be done; greater clarity and intuitive guidelines are needed. A terminology requiring both IL and IT literacy is clumsy. Information competence, ITC literacy, socio-technical literacy, fluency with IT, and all the terms utilized to date cause confusion and hamper focused progress. Information technology literacy is probably the best label available at this time, particularly when used in the socio-technical and contextual sense presented by Talja.^[46]

Technology and Academic Literacies

The new literacies require participation. The level and form of participation is determined by the competence of the participant. Several issues emerge. First, readers become less passive and more engaged as their skills develop. The reader-author distinction fades and texts become fungible, multivoiced, and increasingly unstable. Linking and hypertext—as well as visual and audio media—diminish the role of text. Boundaries fade as discontinuities and disorientation place new demands on the participant and the organization. New “literacies”—particularly IT literacies—move beyond skills and cognitive knowledge into the realm of experience.^[47] Donald Norris and colleagues address the issue as creating a new “technology economy” that requires measurement and improvement. They label the process “action analytics.”^[48] The process they describe involves incorporating workforce factors into educational curricula, utilizing open architectures to enhance access and affordability, and adapting organizational cultures to enable greater collaboration and innovation.

It is obvious that librarians must adapt to the users of new technologies. Today's students—the Net-generation to some, “millennials” to others—are mobile (with cell phones, i-pods, and laptops), collaborative, and “game oriented.” These devices facilitate learning the skills required for the new age, but librarians need to be able to better help them with that use. Students are restless in

crowded lecture halls and impatient with “nonconnected” authority figures, for which a segment of the professoriate and the library profession qualify.^[49]

Librarians by no means have the field to themselves. Other groups and companies are pushing into the arena. Two notable examples are the European/International Computer Driving License certification program and the P21 skills development efforts of the Partnership for 21st Century Skills. Civic and corporate organizations are joining the campaign to assure that more young people have the skills necessary for the new century.

Connectivism

We have not yet discussed adequately the importance of the network and connectivity. The power of the network is widely proclaimed and increasingly self-evident. Its importance in organizational change and development is discussed elsewhere. But how does it work for people and what sort of challenge does it present for IT literacy and libraries?

Scholars and researchers are turning their attention to “connections,” their nature and importance. This is not connectivity, a technological concept that focuses on bandwidth and issues of communication and access. Connectivism is something different, an object of recent interest to select denizens of cyberspace only beginning to turn up in early 2008 searches of mainstream databases, from *Academic Search OneFile* to Elsevier’s *Science Direct*. But influential bloggers promote connectivism as a theory of learning that goes beyond behaviorism, cognitivism, and constructivism to become a learner-driven approach. Not a learner-centered approach, but a learner-driven approach. The very act of joining in, of connecting, signals the engagement of the learner.

In a persuasive argument, Siemens offers connectivism as a “learning theory for the digital age,” a view seconded, disseminated, and discussed from time to time by Downes on his influential *Stephen’s Web* blog. Siemens’ essay is spotty, with weaknesses that include his definition of the half-life of knowledge. But his description of connectivism is captivating. He asserts that connectivism integrates chaos, network, complexity, and self-organization theories. He believes that knowledge begins with a diversity of opinions, is a process connecting nodes of information, and may reside in nonhuman appliances (computers). The theory stresses the nurture of connections to enhance currency, enable the difficult perception of connections across disciplines, and regards decision-making as a learning process.^[50] The learner-driven element is suggested as the distinguishing characteristic of the new decentralized learning. A complementary case is presented in an extensive Australian study. Candy^[51] demonstrates that “learners” are busy collaborating and creating knowledge on their own, independent of their instructors. He suggests that students and learners are far ahead of their

instructors in utilizing networks and personal connections to share and create knowledge informally. Brown^[52] places this trend in a larger context: something very big is underway, a shift from “pushing” information and knowledge through our schools, systems, and media, to a system, a paradigm, whereby people seek and “pull” what they want and need. Jenkins^[53] defines the situation as one of growing technological/media convergence, and points out that the process is as much social and cultural as it is “technological.” It is not the existence of the tools and devices but their use by people at work and play that is transformative. This way of thinking fits nicely into a coherent argument that explains the power of the network through understanding the importance and character of connectivism. Fully comprehending this trend and participating in its development is one more challenge for librarians and information specialists.

Learning and Inquiry

This brings us directly to the process of learning. Libraries have always been places where people can learn. For centuries that is where the information was, in the well-ordered shelves of books, periodicals, documents, and newspapers. But now information is almost ambient, virtual, available at the click of a button. Now the problem is information overload and the learner has different needs, such as selection and evaluation and using the information legally in the variety of formats where it resides. So the librarian’s role is now different. Libraries can still be the places where people learn, but librarians must provide different kinds of assistance. Now the crucial skills have technology components, of steadily increasing complexity.

Information literacy and IT literacy attend the questions of the information seeker. Librarians help the inquirer get from “where they are” to where they want to go. Reference librarians start with the questions of the patron and work to satisfy their information needs. Information literacy and IT literacy give the learner tools to find their own way more effectively; the skill segues directly and smoothly into inquiry methods and “learning how to learn.” Judging by the extent of the literature, Commonwealth libraries are further down this path than their American counterparts in the practices of information literacy leading to inquiry learning.

Knowledge Sharing

Learning leads to knowledge, but generally accepted ideas about knowledge are proving increasingly dysfunctional. Knowledge is Janus-like, dualistic in its complexity. It is simultaneously widely dispersed and personal, articulated and emergent, tacit and codified; it can no longer be sliced definitively into neat disciplines of epistemic practice, but blends across borders into *mélanges* of perspectives.

Its meaning is found in its application to given problems and contexts, not from the quick recall of “facts” for a game show. How knowledge is used increasingly is the product of how knowledge is shared. The traditional “know what,” “know how,” and “know why” proposed by Quinn and colleagues^[54] is supplemented with the networked components of “know who” (authorities, collaborators), “know where” (positioning), “know when” (context, strategy), and “know if,” through scenarios and foresight. New tools and methods of better sharing and utilizing knowledge include institutional repositories, wikis, and other collaborative IT methods producing what has been described as a knowledge-sharing revolution.^[55]

Assessment

There is an important—and political—need for IT literacy to be assessed; we must understand how best to promote it in our schools and across society. Talja presents an important argument that the traditional assessment of computer skills is not the best way to determine needs and capabilities. She proposes that a sociocultural *context* or *domain oriented* perspective is a better approach than the more common user-psychological *generic skills* method. This view takes into consideration the social, interactive, and context-specific dimensions of the issue, suggesting that IT literacy/competence is “dialogic, multilayered, and context-dependent.”^[46] This explanation enriches the literacy–competence–capability approach presented here as an important way to think about the issue.

Others take a more critical view of assessment practice. For some there is too much focus on information processing assumptions and computational-style cognition;^[56] others point to weaknesses in the testing process,^[57] or stress the uncertainty about what can be tested (information gathering and management) and what cannot (understanding and knowledge building).^[58] The aforementioned UNESCO report^[43] makes it clear that there is no agreement on the use of standards and indicators in assessing information literacy; by extension, such is even more the case for IT literacy. The complexities of remaining current amidst rapid technological change render traditional assessment methods questionable. Additional study and alternate approaches are required.

CONCLUSION

New tools can lead to new human capabilities; at that point technologies demonstrate the potential to change society, culture, and the human condition. Today information and communication technologies exercise that power, or at least their potential. To adapt to this situation requires widespread use of knowledge and skills that best can be described as IT literacy, a new fundamental capability that is necessary for effective participation in the

twenty-first century. Librarians are well situated to play a central role in promoting those skills and guiding society in adapting to the new knowledge and lifelong learning requirements.

Information Technology Project Implementation in Developing Countries *[ELIS Classic]*

Athanase B. Kanamugire

Library Consultant, Dhahran, Saudi Arabia

Abstract

Kanamugire's essay is a wise and widely knowledgeable survey of the issues and problems involved in carrying out information technology projects in developing nations. While some of the technology described has been superseded, the broad range of issues addressed and helpful solutions suggested by the author are still pertinent.

—*ELIS Classic*, from 1998

INTRODUCTION

In recognition of the importance of information and information technology (IT) in development, some governments in developing countries, as well as the international community, have implemented IT projects in library and information services in developing countries. The term developing countries is used to refer to the group of countries known as developing nations, Third World, less-industrialized, least-developed, or the South. The World Bank, for example, defines developing countries as those with per capita incomes in 1992 in the range of \$80 to \$12,000, 5% to 64% of their productive resources devoted to agriculture, adult literacy rates of 35–90%, life expectancy for residents from 40 to 73 years, and 10–75% of their populations living in urban areas. The human development index (HDI) developed by the U.N. Development Program (UNDP) is also used to complement the World Bank gross national product (GNP). The HDI index combines life expectancy, educational attainment, and income into a composite index. According to the HDI, developing countries are those with 0.191 to 0.835.^[1] The working definition in this entry, therefore, refers to the many countries in Africa, Asia, the Middle East, the Caribbean and Latin America, and Asia/Pacific, which have different degrees of scientific, technical, economic, and social developments. However, as Mahoney points out, in an immediately postcolonial world there was little argument about what constituted a developing country. Now we have the extremes of Singapore and Rwanda; enormous disparities in population wealth in individual countries, and to cap it all, the end of the Eastern bloc and all the problems of development unleashed there.^[2]

Among the many international organizations that have been involved in implementing IT projects in developing countries, the U.N. Educational Scientific and Cultural Organization (UNESCO) has played a leading role through its various programs, including UNISIST

(UNESCO/ICSU Program for the Development of a World Science Information System), NATIS (the National Information System), and PGI (General Information Program). For instance, UNESCO has underscored the significance of creating databases that can handle locally produced information and facilitate the exchange of information in computer-readable form. One of the objectives of UNESCO is therefore to promote the development and use of software packages for bibliographic and functionally related nonbibliographic applications that implement internationally accepted programs for the exchange of bibliographic data. The UNESCO/PGI program facilitates assistance in the selection, acquisition, and installation of appropriate software packages, training, and provision of hardware, especially microcomputer systems.^[3] Other UN agencies that have supported and implemented IT projects in libraries and information centers in developing nations include the International Atomic Energy Agency, the Food and Agriculture Organization of the United Nations (FAO), the U.N. Environment Program, the U.N. Development Program (UNDP), and the U.N. Fund for Population Activities through its Population Information Network (POPIN) programs.^[4]

Some regional and governmental organizations have also played a major role in implementing IT projects in developing nations. Chief among them is the EEC (European Economic Community), which has sponsored the application of IT to information systems in the ACP (Africa, Caribbean, Pacific States) countries. The Technical Center for Agricultural and Rural Cooperation (CTA) has been instrumental in implementing CD-ROM technology projects.^[5] Besides international and regional organizations, some national government institutions, such as IDRC (International Development Research Center) of Canada, have also played a crucial role in implementing IT projects in developing nations. In Saudi Arabia, for example, the Saudi Arabian Center for Science and Technology (SANCST), currently known as King Abdulaziz

City for Science and Technology (KACST), has developed IT-based national science and technology information systems.

Information, Information Technology, and Development

These international, regional, and national institutions have expended considerable effort and resources in implementing IT in information systems in developing countries hoping that their efforts would lead to information and IT transfer, and ultimately to development. UNESCO has underscored the importance of information in development in a number of documents. The *Final Report of the Intergovernmental Conference of the Planning of the National Documentation Libraries and Archives Infrastructure* underscored that the conference recognized that information has become an essential basis for the progress of civilization and society and that improving human relationships in their own societies and among peoples of different cultures and traditions contributes to better understanding and world cooperation.

The same document further reaffirms document NATIS/3's statement that "Information is not only a national resource vital for scientific and economic progress, but also the medium of social communication." NATIS declares that "access (to information) is one of our basic human rights." Recommendations 14–21 on the application of technology to documentation, library, and archives services are particularly relevant.

Some of the major pertinent recommendations include the following

- Insofar as the systematic analysis of a nation's requirements reveals the need to use modern technology, they enact special legislation or take appropriate measures in order to deploy all the technical applications of NATIS and accept the possibility of cooperation with a view to distributing resources equitably.
- UNESCO should arrange for a study on the feasibility of a file of software packages in the field of documentation, libraries, and archives.
- With regard to the application of technology to documentation, library and archives services, no indiscriminate introduction of mechanized techniques be made into information fields in countries where the technological environment is not ready for them.^[6]

The experience of many organizations involved in implementing IT projects, however, has shown that the role of information and IT might have been overestimated. Due to many problems, especially infrastructural constraints, many IT projects in developing countries have failed. There are indeed three schools of thought on this question. The first school contends that IT would help developing countries "leapfrog" the industrial age into

the electronic age by means of the application of the new technology. Abid claims that "CD-ROM will help libraries in developing countries to leap ahead into the 21st century."^[7] De Horowitz summed up the idealism of this school of thought:

New technologies, it was believed, would extend the benefits of information to all, in forms tailored to individual needs and skills and, hence, would foster development and enhance the quality of life in all nations and throughout all sectors of society.^[8]

While acknowledging the potential role of IT in development, many authors advocate a cautious approach to adopting IT and question the impact of IT in developing countries. Slamecka argues that IT unquestionably evolves in a general direction beneficial to the Third World with respect to both its utility and affordability. However, he concludes that the fundamental problem of the Third World, its poor standard of living of the masses, is caused by low productivity of their agricultural and industrial sectors and by their inability to compete in international markets; hence it is an economic problem. Developmental strategies that fail to address this fundamental point in the hope that developing countries may somehow circumvent it and blossom into postindustrial "knowledge" societies, are utopian unless one accepts the unlikely premises that these basic needs will be provided permanently by someone else and that the Third World can rapidly overcome the highly skewed distribution of knowledge resources.^[9]

On the other hand, it has been contended that developing countries need appropriate IT; that is, IT that suits their stage of development. The proponents of the appropriate technology theory contend that IT is too advanced for developing countries and that economies of developing countries are incapable of acquiring IT, as it is too expensive. They thus recommend that developing countries should continue with manual systems or make do with affordable semiautomatic technology. They argue that technology should match the level of development of a country and must be appropriate to available resources. On the contrary, the opponents of this school of thought assert that the appropriate technology ploy is dangerous because it means that the Third World should always lag far behind in development due to its poverty. Second, the Third World cannot even keep the development pace it could attain with IT. and third, there is an imminent dichotomization of the Third World as well as the development of two worlds within the Third World because the richer among them can afford IT, leaving the poor further behind.^[10]

Despite the criticisms against the role and impact of IT in development, many libraries and information centers have come to realize that the application of IT is a critical factor in their role of providing effective information

services, and thus facilitate effective transfer of information for development. Nonetheless, they have encountered numerous challenges in their endeavor to plan, implement, and manage IT projects. These challenges and possible strategies to overcome them are discussed in the following entries under management and operational concerns.

MANAGEMENT ISSUES

Most of the problems encountered in the implementation of IT projects in developing nations are intrinsically linked to their socioeconomic and political underdevelopment, and hence the existing underdeveloped information infrastructure, such as the lack of information policies. Many problems could be alleviated if there were sound information policies covering the major issues pertinent to the development and implementation of IT projects. Unfortunately, a considerable number of countries are yet to recognize information as a major sector for which policies should be developed. This could be explained by the state of the economic underdevelopment prevailing in many developing countries, whereby the majority live under the poverty line. Under these circumstances, priority goes to these sectors that are vital for meeting essential needs, such as food, clothing, health, and shelter. Since it is generally recognized that sound information policies including IT policies are crucial for successful planning and implementing IT projects, policy and decision makers should be vigorously sensitized on the important role information and IT can play in development. This may be achieved through aggressive marketing of information, especially strategic information to policy makers, planners, and decision makers. Political factors have also significantly inhibited the implementation of IT projects in developing countries. Such factors include instability which hinders the implementation of sustainable IT projects, and censorship against importing some IT equipment, such as the ban against modems during the dictatorship of Dr. Kamuzu Banda in Malawi. Thorpe summarized the political factors inhibiting IT as adopted from Eres as follows: unstable governments, desire for often excessively tight security and secrecy, constantly changing priorities, centralization of decision makers, and lack of scientific impact at the highest levels of government.^[11] The planning of IT projects should normally start with needs assessment. A thorough feasibility study may be conducted to determine the actual and potential needs of the target user population as well as the systems requirements. In conducting a needs assessment study, all parties concerned with the implementation of IT projects should be involved. In fact, it may be useful to form a working group on IT project implementation during the initial phases of planning and IT project. The working group may consist of representatives of all parties that will be involved in or directly affected by the design and

implementation of the projects. The working group may include policy and decision makers or their representatives, actual and potential users, IT departments, other departments of the library/information center, and the sponsoring institution. The objective of creating the working committee is to provide an experienced group of personnel who may steer the project through all its stages and be self-sufficient in appropriate expertise. This approach is appropriate in developing nations since it provides the opportunity to impart professional skills that may not be readily available in the library; thus the project may be completed more quickly. The planning committee would be involved in the development of the vision, strategy, and action plan of implementing IT projects. At this stage it is essential to formulate realistic and attainable goals and objectives, bearing in mind the infrastructure problems, such as financial, political, policy, procedural, cultural, and above all, human resource constraints. It is important to anticipate delays in implementing IT projects. The action plan and especially the schedule should be flexible. During actual implementation many management problems and issues are likely to arise that may delay the implementation of the project.

A number of methods such as informal interviews, structured interviews, questionnaire surveys, and observation and documentary descriptive methods have been employed in needs assessment. The informal and structured interview methods may be effective, as the interviewer can explain concepts that are difficult to understand, and pertinent information may be gathered during the process of interviewing. The main problem with this method in developing nations is that the interview appointment may not be promptly fulfilled and many interruptions are likely to occur during the interview. The questionnaire method has been useful for eliciting information from a large, geographically dispersed population. The problem with the questionnaire survey is that the response rate is likely to be low because of a number of reasons, including apathy. Although documentary or descriptive methods may provide vital data, it is often difficult to get access to institutional documents. There is a tendency to protect or hide information. Relevant documents are often labeled classified. It may also be difficult to have access to documents due to the lack of a system of organizing them.

Another major problem encountered in an attempt to conduct needs assessment in developing countries is the problem of communication. The target audience may not understand the technical jargon used in conducting a needs assessment or feasibility study. Moreover, input from the respondents may not be very useful or very reliable, as many respondents may not be familiar with IT discourse, devices, and requirements. The question of communication is even more complicated when a foreign consultant who does not understand the cultural and political milieu conducts a feasibility study. Such a consultant may often

end up formulating unattainable goals and objectives or issuing unworkable recommendations due to the lack of understanding of the socio-cultural, political, and economic environments. Projects implemented according to the “inappropriate” objectives and strategies prescribed by such consultants are often short-lived, nonsustainable, and doomed to failure. Dosa contends that the success of projects dealing with the design, management, and evaluation of information systems or the development of library and information science curricula are especially dependent on the consultant’s sensitivity to local conditions.^[12] Knowledgeable as they might be in their fields, technical advisors might become frustrated and impatient with their local counterparts if the advisors lacked practical experience with the host country’s traditional approach to changes. Mustapha stresses the need to develop clear guidelines for consultancy work in developing countries to ensure the success of future consultancies in these countries. His recommendations below are based on IFLA’s Standing Committee on Theory and Research Panel discussion at the IFLA general conference held in Manila in 1980.

1. The consultant should have an adequate knowledge of the politics, culture, history, manners, customs, language of the host country, and a thorough knowledge of library services and their administrative problems in the region/country.
2. The consultant must have good public relations skills to enable him to deal with high-ranking officials in the host country, thereby winning their confidence.
3. A clear definition of the problems and realistic expectations as to the goals and objectives of the project and a prior agreement between the consultant and the host country on the objectives of the consultancy is therefore deemed necessary.
4. There is a need for involvement of local librarians at all levels of activity, with emphasis on project continuation beyond the term of the consultant’s tenure.
5. There is a need for more contacts between the consultants and librarians and other information specialists in the host country, rather than concentrating too much on their own meetings with government officials who are influential, but who hardly understand ambiguous, and full of jargon and highly technical phrases.
6. There is a need for multi- and interdisciplinary consultancy. Such an approach may be more productive and successful than those undertaken by specialist consultants working alone.
7. Consultants should participate in the implementation of the mission’s recommendations.
8. Aid agencies should take more active roles in the implementation of consultancy rather than leaving this aspect of the outcome to the recipient countries; consultancy missions should be coordinated to avoid duplication of effort and to ensure follow-up reviews of recommendations.^[13]

In order to address some of the problems related to the language barrier, simple terms familiar to the target audience may be used in designing the interview or the questionnaire. Technical jargons familiar to the information professionals but not familiar to the respondents should be avoided. Using local information professionals who understand the local environment and local languages as consultants may help to elicit more information. They would not only translate the questionnaire into local languages, but through their influence and understanding of the local politics, policies, and procedures, they may also easily have access to essential documentary sources. They may count on their personal contacts, which are quite important not only in needs assessment, but also in the whole process of implementing IT projects in developing nations. Should it be necessary to recruit an external consultant, he should then work closely with a national counterpart.

Human Resource Concerns

Apart from the question of consultants, there are other equally significant human resource challenges faced by information systems in developing nations. These challenges range from a lack of qualified and experienced information professionals to a lack of appropriate staff development opportunities. The low status, meager salary, and lack of other fringe benefits of information workers may mean that the information profession does not attract the most competent and qualified personnel. Ideally, the person responsible for the implementation of an IT project should combine IT and library or information science qualifications, skills, competencies, and experience. In some cases, subject background or qualification in the subject of interest of the parent organization is desirable. It is difficult to recruit people with such qualifications. Even when competent personnel are recruited, it is often difficult to retain them because of unsatisfactory conditions and terms of service. Some join other institutions that offer better salaries and fringe benefits within the country, while others migrate to the so-called greener pastures.^[14] Wesley underscores the scale of the brain drain of qualified and experienced manpower in the Sudan, where over 40% of the professionals, 13.5% of the para-professionals, 23% of the clerical workers, 11.75% of the nonlibrarian graduates and 11.75% of all others, had migrated from the Sudan in 1985.^[15]

The needs assessment exercise would be useful in determining human resource requirements. There may be a need to recruit new members of staff. In such a case it is advisable to recruit computer-literate information professionals or computer professionals who are knowledgeable in library matters. Those who lack computer skills should at least have an interest in computers and the willingness and aptitude to learn and acquire computer skills. In order to avoid nepotism, corruption, and other kinds of

malpractices rampant in many developing countries, it is advisable to form a broad-based committee to deal with recruitment issues. Recruitment may involve three types of staff categories: nationals, consultants, and expatriates. One of the critical factors that should be taken into account in recruiting expatriates is their ability to adopt to local conditions. Apart from their professional/technical expertise, their experience in developing countries should be a credit. Unfortunately, it is not easy to recruit someone who combines both IT expertise and local experience. If possible, an information system may recruit both expatriates from the West as well as those from developing nations. In order to develop a sustainable IT project, it is essential that one of the major roles of expatriates be to train the local counterparts who will ultimately take over from them. A strategic plan to this effect should be developed and implemented. Many libraries and information systems may not be able to afford recruiting expatriates, but they may rely on development or humanitarian aid agencies in the recruitment of different types of experts. Some voluntary organizations, including the U.N. Volunteers, British Volunteers Overseas (VSO), and the U.S. Peace Corps provide expertise and assistance that involve training of national counterparts. Also, many NGOs, such as the British Council, the Ford Foundation, and the Rockefeller Foundation, have assisted in developing library, documentation, and information services in developing countries.

The problem of a shortage of qualified human resources may be alleviated through offering such staff development programs as in-service training, on-site training, workshops, short courses, symposia, study tours, seminars, meetings, self-instruction, distance learning, and internship or attachments to another library. Participation in seminars, symposia, conferences, and meetings are useful for providing information on the latest developments in IT. Short courses may be useful for providing basic or up-to-date information in a particular IT area. However, a major criticism of many short courses is that too much is covered within a short period. Moreover, some short courses are not tailored to a specific level of audience. Training should be an essential component throughout the various stages of project implementation. It should figure high up in the project proposal document. A comprehensive program including all categories of staff and encompassing training during the preimplementation, implementation, and postimplementation phases should be developed. Training may start with conducting a user sensitization program for policy makers and managers. This may be conducted in a center of excellence where a similar project was successfully implemented in a developing nation or a developed country. The rationale behind such sensitization programs is that policy makers would develop appreciation of the benefits of implementing IT projects and would hopefully support IT implementation projects in their own organizations. Apart from policy and

decision makers, another group needing training during the initial phase of the project comprises potential trainers, including systems librarians and/or persons from the computer services responsible for library IT projects. It is crucial to select the right person for training. In addition to appropriate aptitude and interest, the person to be trained as a trainer should also have the will to share with his colleagues the skills acquired during the training. Unfortunately, this is not always the case. In order to offer an effective IT training program, it is important to involve all the concerned parties—sponsoring agencies, international and national consultants, and institutional library and computer services department staff—in organizing and conducting the training. This strategy was adopted successfully by the University of Singapore in 1980 when it implemented a project of the MINISIS test program for an integrated system at the library of the National University of Singapore. The MINISIS project committee set up to prepare a program for staff training comprised the heads of major library departments and a systems analyst from the computer center.^[16]

Other major training issues that should be borne in mind are timing, duration, venue, content, format, method, and evaluation. The timing of training should not coincide with other activities that may be going on in the organization. Some training should be offered prior to, during, and right after the implementation of an information project. Training should indeed be an ongoing activity throughout the life of the project. This is important to enable staff keep abreast of the latest developments in IT. The issue of whether training should be offered on-site, within the country, or abroad deserves serious attention. If well-planned, on-site is valuable, since many staff members are likely to benefit from it. Moreover, some of the practical problems peculiar to a particular environment may be more appropriately addressed. On-site training is particularly useful for training staff who would be directly involved in the day-to-day operation of the IT project. Training abroad, especially in industrialized countries, is useful for planners and decision makers, systems librarians, and other senior staff members who would be involved in the actual planning and implementation of the project. Training within the country or region is useful especially for new graduates who have pursued studies in developed countries in which the IT environment differs from the situation prevailing in many developing countries. Such training is desirable to help the new graduates reorient themselves and marry theory learned in library information science schools to the actual IT environment in developing nations.

By and large, the content of the training program should be determined by the level of IT literacy of the targeted staff members as well as their functional responsibilities. For example, a microcomputer training package for information workers without computer background may include: operating systems, microcomputer hardware

and software (especially database management software packages), data and file management, word processing, desktop publishing, generation of reports by using microcomputers, and application of microcomputers in the various functions of an information system; that is, management; acquisition; information processing such as indexing; abstracting; information retrieval, including CD-ROM searching; online searching; access to network resources, especially the Internet; and electronic information marketing. Training programs are often carried out with no significant tangible impact. It is therefore imperative to evaluate the training programs on a regular basis and to modify the objectives, content, methods, and formats in response to the feedback obtained and lessons learned.

Financial Resources

Probably the most critical management issue facing information systems in developing countries in implementing IT projects is the lack of (or inadequate allocation of) financial resources. To make matters worse, many of the materials needed for implementing IT projects in developing nations must be paid for in hard currency, which may be difficult to come by. Furthermore, information systems have to undergo cumbersome bureaucratic procedures in order to obtain the necessary financial resources. To solve this problem, information systems should strive for allocation of an adequate budget for implementing or developing IT projects. Enough financial resources must be allocated to meet (a) the initial investment cost, the purchase of equipment, and the construction of buildings, (b) the recurrent costs for personnel salaries, staff development, interlibrary loan and document delivery, and (c) the acquisition of documents. Financial assistance may be sought from international donor agencies; however such external assistance may be useful as an interim measure in implementing and developing IT projects. It is not a durable solution. Recipient institutions should therefore develop some mechanism that would lead to institutional self-reliance. In addition to seeking funds from donor agencies, library information systems should endeavor to raise funds from internal institutional or other national sources. Academic libraries may seek assistance from academic and research programs that benefit from library IT resources and services. They may also exploit the possibility of hardware and software donation to the library. Value-added information services may be provided to policy and decision makers to sensitize them to the importance of information and hopefully win their financial support. Information systems may also carry out some income-generating and fund-raising activities as well as charge for some services in order to ensure the sustainability of the project at the end of external financial assistance.^[17] However, such charges may not be in the interest of the disadvantaged majority who cannot afford

to pay the fees. This practice may indeed widen the gap between the minority haves and the majority have-nots. This is not desirable in most developing countries.

Hardware and Software Options

In addition to human and financial concerns, issues related to hardware and software options such as their selection, procurement, installation, and maintenance are equally important in implementing IT projects in developing nations. Results of the needs assessment study would be useful in determining hardware and software requirements. To many information systems in the Third World, mainframes and minicomputers are too expensive to purchase and maintain. A considerable number of information systems in developing countries have therefore opted for microcomputers. Not only are microcomputers relatively cheap, but they are also easy to install and use. Moreover, they are readily available in the local markets, although purchasing microcomputers locally is more expensive than ordering them from abroad. Besides, technical support, maintenance, supplies, and training are locally available.^[18] Furthermore, microcomputers allow some kind of autonomy. Opting for mainframes or minicomputers may mean a bond with the computer departments. Experience has shown that libraries and information centers do not often get the necessary priority from computer services departments. Also, many powerful microcomputers have emerged, and through networking they may perform the same tasks as those performed by mainframes or minicomputers. Moreover, donor agencies are more willing to assist in developing microcomputer/mini-based information systems through the provision of hardware and software packages than to assist in developing mainframe-based information systems.

Although hardware and software options may be primarily determined by the requirements as ascertained during needs assessment and the application to which they would be used, it is advisable to opt for powerful and durable hardware as well as user-friendly software systems. Due to rapid developments in IT, and particularly in the use of software packages that demand a lot of memory such as Windows '95 and multimedia products, it is advisable to opt for a powerful and fast PC with a massive amount of memory. Cost and durability are crucial factors in selecting hardware and software packages because of the existing harsh climatic conditions in many developing countries coupled with the inexperienced hands of some staff members and the uncertainty of acquiring new equipment or upgrading the machine due to financial constraints. Compatibility is still a major factor for sharing information and IT resources in view of the lack of a standard hardware and software interface and the scarcity of resources in developing nations. As IBM is still the de facto standard in the PC world, it is advisable to opt for IBM or IBM compatibles or Macintoshes with a great

amount of memory and considerable expandability. Only computers manufactured by well-known companies such as IBM, Compaq, Apple, Power Computing, and HP should be used.

With regard to the acquisition of peripheral hardware, the options for printers should be primarily dictated by durability, quietness, and simple operation. Dot-matrix printers are relatively cheap, simple to operate, and fast; however, they are unsuitable for public access services since they produce a high-pitched noise. On the other hand, if an information system needs high-quality print, especially if the printer is to be used for desktop publishing, a laser jet printer would be more appropriate. In view of the existing IT environment, especially the Windows and multimedia environment. SVGA or XGA monitors should be purchased. As for Keyboards, bilingual, heavy-duty one's are recommended. The selection of communications hardware components should be determined by the existing communications IT. Power stabilizers and regulators such as power surges or uninterruptible power supply (UPS) are indispensable in most developing countries because of frequent power interruptions.

There are many problems related to the use of IT hardware in developing nations. These include such environmental hazards as dust and humidity, and natural disasters such as those caused by the Harmattan in Nigeria, hurricanes in the Caribbean, or typhoons in the Pacific. Dust leads to floppy disc failure as well as to the use of more ribbons than usual. To alleviate these problems, printers and floppy disk drives should be covered with polyethylene bags. The snag of voltage variation common in many developing nations, in which there are few power stations that are able to provide a continuous supply, may be partly solved by using a noninterruptible, surge filter supply, or UPS. Car batteries could be used, but as observed in Nigeria, they are subject to theft. Instead of car batteries, cadmium rechargeable batteries may be used, since they are seldom used in many developing nations and therefore not recognized by thieves.^[19] Given the shortage of spare parts in developing nations, it is imperative to include a wide range of supplies, including ribbons, toner, and plugs in the project budget.

As for the application software options, designing in-house software packages may not be the most appropriate option. First, most librarians in developing nations lack the expertise to design or use in-house software. Second, developing in-house programs is rather expensive and time-consuming. Since a lot of software packages suitable for a variety of library applications are available, libraries and information systems in developing countries should opt for such packages. These include CDS/ISIS, In-Magic, D-base, Sci-mate and Knowledgeman, Microsoft Access, and Excel. Among these, CDS/ISIS is the most widely used package, primarily because nonprofit organizations of UNESCO member countries obtain it free from UNESCO. Moreover, installation can be done through

CDS/ISIS local or regional offices such as ARSO in East Africa or ALESCO in the Middle East. Besides, the package comes with very clear instructions on how to install the system and there are many users, including CDS/ISIS user groups, who can offer installation and other assistance. Micro CDS/ISIS enables information systems to define a database structure, enter new records, and modify, edit, delete, retrieve, sort, display, and print existing records. CDS/ISIS can be used for most major library functions, including library catalogs, serials holdings, union lists of periodicals, union catalogs, and bibliographic and referral databases. On the other hand, CDS/ISIS has been criticized for lack of user-friendly documentation as well as search software interface.^[20] Other two software packages that have been widely used in many developing nations are In-magic and dBase. In-magic can handle catalogs, acquisitions, serials control, current awareness, and loan service systems. It also offers a password facility for file security purposes. The major shortcoming of In-magic within the context of developing nations is that it is expensive. D-base, a general-purpose database management software package, allows creation of a database with customized fields, updating, editing, sorting, indexing, printing, and a combination of concepts by using Boolean logic operators.

There is a plethora of micro-based software packages that can be used in specific library functions in developing nations. Ventura and Page Maker may be used for desktop publishing, while LOTUS can be used for statistical purposes. WordPerfect, MsWord, and Windows'95 have been widely used for word processing. Besides micro-based software packages, a number of mini- and mainframe-based automation systems are preferred in developing nations, mainly because they are supplied free to nonprofit organizations in developing countries or because they are bilingual. Such systems include MINISIS, which runs on HP minicomputers. MINISIS has been extensively utilized in Africa, Asia, the Middle East, and Latin America. DOBIS/LIBIS, a bilingual integrated library system, has also been widely used in the Middle East. Recently a new bilingual system, Horizon, which has a vendor in the Arab world, was introduced. The Arabic version was developed by Ameritech Library in cooperation with Arabian Advanced Systems. In addition to the Dynix minicomputer-based and the NOTIS LM8 mainframe-based systems, it has rich functions and features. The Horizon automated library system provides a graphical user interface standards-complaint, industry-leading database management system and a client server processing model that allows the system to operate on an unusually wide range of hardware platforms.^[21]

In selecting software packages for information systems in developing nations, the application for which they would be used as well as the existing software and hardware IT environment should be taken into consideration. The *Datapro Guidelines* for software selection, which

consists of ten logical steps for selecting software for any computing systems, could be adopted. These steps are: determine the requirements, gather information on the existing systems, draw up a short list, perform a detailed evaluation, review previous users' experience, conduct a benchmark, make a final decision, negotiate a contract, install the package, and check the results. These steps need modifications, however, taking into account the unique circumstances prevailing in developing nations. The *Datapro Guidelines* have been criticized for having too little regard for the user and his or her environmental constraints. To solve this problem, Bell recommends that users should be given details of existing systems and the potential users should be allowed to reevaluate their requirements.^[19]

Having selected the hardware and software platforms, library information systems may encounter numerous problems in their procurement and installation. Although the purchase of hardware and software systems from computer dealers in developing nations promises reliable technical assistance in installing, training, providing supplies, upgrading, and procuring hardware and software packages, it is more costly than purchasing them from developed nations. Any problems faced in installation and maintenance may not be easily resolved if there is no local dealer to provide technical support, and the requisite training may not be provided. Consequently, one ends up with delays in the installation of the systems, or in some cases the systems are never installed. Even if installed, breakdowns that are likely to occur may not be resolved due to the lack of spare parts and technical assistance. In the final analysis, it may be more cost-effective in the long run to purchase hardware and software systems from the local market, if available. On the other hand, procurement of such items from industrialized countries may take a long time in processing paperwork, applying for import licenses, using foreign currency, and paying for customs clearance and tax. Referring to her experience in implementing information projects in Yamen, Hutchinson refers to the lengthy bureaucratic and technical obstacles that delayed the arrival of a microcomputer and a mini-computer.^[22] Johnson asserts that procurement invariably takes twice as long as purchasing agents estimate. Procedures for purchasing, tendering for suppliers, and waiting for equipment to be supplied and delivered all add up to the general time frame required. In her experience in Bangladesh, equipment procurement was estimated at 3 months, but it took over a year, as a result of both donor and host country procedures.^[23]

Once acquired, a suitable siting of the hardware may be selected, taking into consideration accessibility, security, visibility, and future expansion of the facility. Some of these factors may be conflicting; for example, accessibility and visibility vis-à-vis security. In view of the difficulty of obtaining replacement hardware in case the system is damaged or stolen, many libraries, including the

University of Dar es Salaam in Tanzania, the Faculty of Medicine of the University of the West Indies in Jamaica, the University of Nairobi in Kenya, and Makerere University in Uganda, have decided to locate equipment in secure offices that are not easily accessible to the public. An equally important problem regarding the location of equipment is a lack of adequate space to house the hardware, users, and staff. To solve this problem, some rearrangement by weeding out the collection and reallocating staff, equipment, and information resources may be done. The installation of IT equipment may also pose problems. In order to expose library staff to the intricacies and issues involved in the installation as well as to impart skills that may be useful in installing and troubleshooting in the future, library staff members responsible for the day-to-day operation and management of the IT system should be fully involved in the installation of hardware and software systems. Citing her experience in Pakistan, Johnson explained that there was only one electrical outlet in a room that was to house two computers and two printers, including one UPS and two stabilizers. The Department of Works staff was called in to add the necessary wiring and fabricate the required bars. The librarian realized how important it was for him to be involved in the design of the electrical plugs since the equipment would be moved in a few months to remodeled headquarters and he did not want to have to go through the same process again. Working with the electricians, the librarian designed modular power bars that would meet both current and future needs.^[23]

Cultural, Organizational, and Other Barriers

Cultural barriers have also inhibited the implementation of IT in developing countries. Chief among them is the language factor, whereby the languages of the developed nations dominate IT products. These languages are not understood by the majority of the people in developing countries. The efforts that have already been made at the international, regional, and national levels to use the languages of developing countries, such as Arabic and Chinese, in documentation and information processing should be continued. Another cultural barrier is the lack of a reading culture. It is no wonder, therefore, that many IT projects have been implemented only to be underutilized. This problem may be addressed through fostering and nurturing a reading habit through the major social and educational institutions such as the family and primary, secondary, and tertiary educational institutions. The provision of adequate reading facilities such as different types of libraries can also play a major role in promoting reading. Other cultural constraints include the time concept or the general slow pace of doing things and the significant role of personal contact and influence that adversely affect the implementation of IT projects.

Other problems related to management include organizational and restrictive, protective control measures. The organizational issue is particularly a problem in documentation or information centers. Such centers are usually affiliated to parent organizations that consist of other divisions or units that are often considered more important than information centers. Indeed, information centers are often considered so unimportant that in some cases they are regarded as support units of the lowest order, and consequently they are often allocated unqualified personnel and inadequate financial and material resources. From the initial planning, efforts should be made to ensure that information centers rank high in the organizational structure of the parent institution. The head of the information center should be on par with the heads of major divisions in the organization and report directly to the chief executive officer. Restrictive control measures practiced by many information centers serve as barriers to easy and convenient access to information. As a result, the target users avoid using information services. There is therefore a need to liberalize procedures that limit access to information, such as a unnecessary filling out of forms, the need to obtain approvals prior to admittance to the library, and limited access to some essential information sources and services.

These problems cannot be changed overnight; nevertheless, they must be taken into account in planning and implementing IT projects. Flexibility, development of realistic schedules, and personal contact and influence must be taken into consideration throughout the planning and implementation of IT projects. Some of the cultural constraints may be overcome through the involvement of local or national human resources in the implementation of IT projects in developing nations. Other major problems and issues, such as the inadequate existing information infrastructure, will be discussed in detail in the entry below on operational issues.

OPERATIONAL ISSUES

Information technology has been applied to a variety of operational functions of library and information services in developing countries. These functions include information retrieval, dissemination of information, information processing, collection development, interlibrary loan and document delivery, and user training. In information retrieval, IT has been utilized in accessing remote online databases, searching CD-ROMs, searching network resources, and developing local databases.

In information processing, IT has been employed in developing bibliographic, referral, numeric, and full-text databases. In interlibrary loan and document delivery, IT has enhanced the efficiency and effectiveness of identifying and transmitting requests, along with supplying and delivering documents. Information technology has also

played a major role in the dissemination of information through current awareness services and selective dissemination of information.

Online Searching

Probably the earliest application of IT to information systems in developing nations was for accessing international commercial online databases. Some developing nations in Latin America have been at the forefront in this regard. The use of DIALOG from Latin America began in September 1975, when the Seccion de Consultas en Bancos de Information (SECOBI) of the Consepcion Nacional de Ciencia y Tecnologia (CONACYT) in Mexico established an account. Besides DIALOG, Latin American institutions also used other online systems, such as SDC, ORBIT, and NLM. In 1979, the Bibliotheca Regionale de Medicina (BIREME) in Brazil established the *Index Medicus Latino-Americano*, submitting citations to NLM from regional publications for inclusion in the larger databases sponsored by the Pan American Health Organization, the World Health Organization (WHO), and the Brazilian government.^[24] The late 1970s and early 1980s witnessed the development of online access in the Middle East and the Far East. Some of the developing countries that pioneered in online searching during this period include: Brazil, Mexico, the Philippines, Hong Kong, Iran, Taiwan, Singapore, the People's Republic of China, Ivory Coast, Saudi Arabia, Senegal, South Africa, Egypt, Tunisia, and Ethiopia.^[25]

A number of reasons have been given for the use of online searching services in developing countries. The principal ones are to access a vast amount of relevant, up-to-date, and accurate information that may be used for development; to augment the poor local information sources; to complement other media, such as CD-ROM when retrospective information is needed; and to search multiple and diverse online databases provided by a particular or different online information service provider(s). In his case study at the Institute of Applied Science and Technology (IAST) of the Republic of Guyana, Bahaa El Hadidy concluded that CD-ROM databases alone cannot satisfy all IAST information needs adequately, and decided that an online search access to international vendors was judged necessary to supplement the use of CD-ROM searching.^[26] Many institutions have opted for online searching in order to consolidate and enhance their access to science and technology activities. This was clearly stated in a document prepared by the National Science Foundation in 1979 on the establishment of the Saudi Arabia National Center for Science and Technology (SANCST). The document asserts that the single most effective thing that SANCST could do was to strengthen Saudi Arabia science and technology activities at that point in their development. It was further pointed out that the most effective way of providing science and

technology information was through online searching for information that would be used for planning research programs, identifying individuals and organizations for consultancy, identifying foreign technology for application in Saudi Arabia, and identifying research designs, methods, and patents.^[27] Bourne has proposed that the use of online facilities can be cheaper than trying to improve the library collection in many locations in developing countries, and adds that despite problems such as poor telecommunications facilities and the expense of direct mail, computer-based reference services could be used to augment local information resources.^[28] Although the importance of online searching in developing countries has been recognized for a long time, many Third World countries are yet to take full advantage of online searching due to a number of constraints. Essential components of information infrastructure such as economic, manpower, cultural, and political, inadequate physical facilities, and poor or nonexistent information policies and plans constitute some of the major factors that have inhibited effective implementation and use of online searching. Highlighting the interdependency of the various elements of information infrastructure, Mahon asserted that without parallel development of not only documentation stores but also the skills in information service development and database and databank development and training, the simple availability of technical access is insufficient.^[29] Many developing countries can hardly afford the initial cost or investment of setting up an online search service. It may also be difficult to meet recurrent costs such as connect time charges, printing and downloading costs, annual subscription fees, staff development costs, and system upgrade charges. Libraries are rarely allocated adequate online searching budgets.^[30] Discussing the problems associated with initial investment and recurrent costs, Brito pointed out that the installation of an online database requires a large initial commitment of funds and must be expected to generate high recurring costs. He further argues that in developing countries a number of factors combine to make online searching highly costly: the use of public telecommunications is usually very expensive in comparison to the cost of living; the unreliability of the public telecommunication systems, frequently interrupting a call, may turn a simple remote database search into an expensive nightmare of repeated unsuccessful attempts; and the inexperience of the infrequent users results in excessive search time, thus increasing the telecommunications costs considerably.^[31]

The question of human resources has also inhibited the effective development of online searching in developing nations. Many information professionals lack skills and experience in automated information retrieval. Training courses, like those offered by online information services providers, are nonexistent in many developing countries. The unavailability of funds also makes it difficult for information professionals to attend online searching

training courses or to participate in pertinent staff development activities. Those who pursue course in online searching through their formal education or special training soon lose online searching skills for a number of reasons. For example, they may not have the opportunity to practice online searching or to sharpen their skills because their institutions do not have an online searching facility. Furthermore, they often lack subject background that is crucial for better understanding the information needs of the users and for formulating an appropriate information search strategy. Even when an online searching facility is available, a number of reasons may account for the underutilization of online searching. Probably the most important factor is the fact that potential users are not aware of the existence and availability of the service. Those who are aware of the potential benefits of online searching neither appreciate its importance in their work nor know how to use online searching services. They also lack online searching information retrieval skills.

Another major reason that partly explains the underutilization of online searching in developing countries is the frustration experienced by users in accessing or using online searching services. Users are often frustrated when they do not obtain adequate, accurate, and relevant information. This is particularly the case with the users interested in literature in developing countries. The bulk of literature included in most online databases understandably has a strong coverage bias of literature from developed countries. To make matters worse, users from developing nations may not have access to desired databases because of financial constraints coupled with other barrier and control measures. For example, access to the *TULSA* database has for a long time been allowed to institutions that also subscribe to the prohibitively costly print *Petroleum Abstracts*. Other common frustrations experienced by users include document unavailability, prohibitive costs, technical difficulties of transmitting full-text or image databases electronically, and delays in receiving documents ordered through interlibrary loan. This problem of delays in interlibrary loan and document delivery services has been clearly highlighted in a recent study conducted in Saudi Arabia. A significant number of respondents complained about document unavailability and document delivery delays. One of the respondents commented that

The citations obtained from these sources are usually not available in the library. They are reports of Laboratory/Institute or theses/dissertations or articles in some periodicals which are not available in library. The time for procurement is long and usually when it reaches the university, the need for it is over, or it is found that it is not very useful.^[32]

This issue has been extensively discussed in the literature on online searching in developing countries. In his study

on delayed online searching in Egypt, Al-Hadidy showed that the elapsed time between the search requests and the output delivery was substantially high, ranging from approximately 20–83 days.^[33] Munn has recognized that the introduction of computer services without library backup is counterproductive in that it raises a user's appetite, and with it the frustration in not satisfying the appetite, thus turning him or her away from information services.^[34]

Although there are numerous problems that have inhibited online access to remote databases, some information systems in developing countries have carefully adopted various temporary and durable alternatives. Such options include submitting and receiving search requests by mail, telex, or fax; using a national government or commercial telecommunications service; accessing online services through telecommunications services of another country; twinning with another institution in the developed world; and establishing full direct access to online databases through such telecommunications services as Tymnet or Telenet (and recently accessing online databases via the Internet). In Egypt, the National Information and Documentation Center (NIDOC) first had access to U.S. online databases through the Georgia Institute of Technology library system. Search queries initially developed at NIDOC were transmitted via telex from Egypt to a U.S. intermediary (at Georgia Tech.), who in turn conducted the online search using the search formulation developed in Egypt, but also exercising the option of optimizing the search strategies online.^[33] In Saudi Arabia, the University of Petroleum and Minerals (UPM) library started using online databases in the United States in 1979 by submitting search requests to DIALOG by telex and receiving search results by mail. Later it had access to DIALOG and ORBIT through Bahrain Telecommunications Company (BATELCO). Government institutions in Saudi Arabia without their own access to commercial online databases can benefit from the online search services of the KACST, the national institution responsible for promoting and encouraging applied scientific research and for coordinating the activities of scientific research institutions in accordance with Saudi Arabia's development requirements.^[35] In China, a connection was initially made via Cable and Wireless (HK) Ltd. through the agency of the China Overseas Building Company Ltd. (COBDC) in Hong Kong in 1980. Users in China were restricted to access by postal request. In 1983 the Institute of Scientific and Technical Information (ISTIC) of China established a data communications link ESA-IRS between Beijing and Rome for access to the databases on the vendor system. This was later extended to link up with the U.S. telecommunications networks Tymnet and Telenet. The following year, ISTIC gained access to DIALOG and ORBIT, and a connection to STN in Germany was made in 1986.^[36]

In spite of the significant options adopted by the various developing country regions to access online databases, only limited access has been achieved by most developing countries, mainly because of financial constraints. Some countries adopted interim measures to alleviate financial constraints. Such steps include seeking technical assistance from international, regional, and national organizations, as well as NGOs. That kind of assistance could be useful in establishing an online search service, including carrying out a feasibility study, procuring and installing hardware and software systems, and providing document delivery services, training, and evaluation. However, self-reliance should be nurtured and fostered throughout the implementation of an online search service so that the recipient institution would eventually finance the entire project.

Other measures that may be taken to solve the problems of funding online searching include income-generating activities and nominal charges. To alleviate the bottlenecks of telecommunications, transitional options such as delaying online access or using satellites for accessing online databases may be useful. In order to promote greater use of online searching, adequate publicity of the service to policy makers and planners, academics, professionals, and other potential users should be repeatedly carried out. It is particularly important to publicize the service prior to, during, and after the launching of the service. Since policy and procedural control measures account for the underutilization of online services, such restrictions on use should be avoided or minimized in order to stimulate and accelerate the use of online services. Over the past decade, information systems have tried to overcome some of the problems associated with online searching by opting for CD-ROM. Online searching is used to supplement CD-ROM when most up-to-date or comprehensive information is needed, when one needs to search multiple databases or different online systems, or when the required retrospective information is not available through CD-ROM searching.

CD-ROM Searching

To many information systems in developing countries, the advent of CD-ROM technology has been a blessing. The advantages of using CD-ROM in developing nations abound. These include access to a massive amount of bibliographic, numeric, referral, and full-text image information, broad user base, user-friendliness, convenience of use, relevance, speed of information retrieval and document delivery, portability, durability, exposure to information retrieval skills, space saving, suitability for resource sharing, image raising, added value services, and development of local CD-ROM databases.^[37] On the other hand, CD-ROM has been subject to a number of problems and criticisms. Some of the major criticisms are content relevance, lack of search software interface compatibility,

lack of funds or allocation of inadequate budget for CD-ROM, costly hardware and networking licensing, technical problems such as head crashes, breakdown of UPS, compatibility problems, manufacturing defects, currency, inadequate retrospective coverage, material and financial resources, document unavailability, inadequate user training and documentation, lack of awareness of what is available and how to access it, lack of computer experience, delays in implementation schedules, inadequate human resources, security problems, slow access time, lack of simultaneous access to multiple databases, ownership issues, end-user misconceptions, maintenance problems, endlessly increasing demands for quantitative and qualitative enhancements, and increasing demand for more and different types of databases.^[38]

In spite of the above problems, many library information systems have implemented CD-ROM projects because the advantages of CD-ROM far outweigh the disadvantages. Prior to implementing CD-ROM projects, institutions should start with conducting a needs assessment or a feasibility study to determine whether there is a genuine need for a CD-ROM project. The feasibility study should also assess the adequacy of the existing IT infrastructure, including the IT environment and material, financial, and human resources. Access to national, regional, and international information network resources must also be assessed and taken into consideration prior to deciding whether a CD-ROM project should be implemented. The potential beneficiaries of the CD-ROM service, the staff of the information system as well as the staff of the computer center who would be involved in the implementation, maintenance, and evaluation of the CD-ROM service, should participate in the needs assessment exercise. In fact, it is important to create a planning committee consisting of representatives of all concerned parties.

Since users and representatives of the various interested parties may not understand CD-ROM technology, it is crucial to provide simple basic information on CD-ROM in a handout or information leaflet format, including the advantages of CD-ROMs and the different types of CD-ROM databases. Potential users may be requested to suggest some pertinent titles. However, such suggestions should be critically reviewed by the information professionals. Users tend to recommend whatever they feel may be relevant to their individual or departmental information needs without taking into account the needs of other users or departments. This may lead to developing biased CD-ROM collections or acquiring specialized databases that may not be heavily utilized.

The data and results of the needs assessment study would be useful in determining whether or not a CD-ROM project should be implemented; how it should be implemented; what hardware and software platforms including databases would be required; the type of human resources that would be needed; the necessary planning,

management, and operational functions and activities; and how the CD-ROM project would be evaluated. The results should also be useful in developing the CD-ROM project vision and project document that may include: short-term, medium-term, and long-term goals and objectives of the project, activities that would be carried out in the planning, management, operation, evaluation, and development of the project. In developing a CD-ROM project document it is quite crucial to set goals, objectives, and schedules that are attainable in light of the immense political, economic, cultural, and technical obstacles that are likely to be encountered in the planning and implementation of the project. In most developing countries, financial factors constitute the single most important factor that would determine whether a CD-ROM project would be implemented successfully. It is therefore important to develop a honed project that would be used to seek funding from the parent organization or from external donor agencies.^[39] A sound methodology on how the CD-ROM project would be implemented, and how the sustainability of the project would be ensured through local institutional support, reporting, monitoring, and evaluation mechanisms should be included in the project document.

Since many information systems in developing countries cannot afford procuring, maintaining, and developing CD-ROM systems, many international, regional, and national organizations, as well as NGOs have financially assisted information systems in developing CD-ROM services. The U.N. Fund for Population Information Activities has contributed to the production and distribution of *POPLINE*; WHO and the Pan American Health Organization (PAHO) have played a key role in the development and distribution of the LILACS database. Other organizations that have contributed to the development of CD-ROM systems and services in developing nations include the World Bank, IDRC, USAID, and the British Council. The EEC (European Union), in cooperation with the Tropical Institute of Agriculture in the Netherlands, has also successfully implemented CD-ROM projects in ACP countries.^[5] Some developing nations, especially the oil-rich countries in the Middle East and the Tiger economies of Southeast Asia have financed the production, implementation, and development of CD-ROM products and services. In Saudi Arabia, the National Standards Organization (SASO) has produced Saudi standards on CD-ROM in cooperation with the Arabian Advanced Systems. Also, KACST CD-NET, a national network of over eighty bibliographic, full-text image, and numeric databases held by KACST, can be accessed by Saudi government institutions.

The needs assessment results are useful in selecting a CD-ROM system. In consideration of the rapid developments in IT, it may be difficult to recommend specific CD-ROM hardware and software components; however, it is advisable to opt for IBM or IBM compatibles or

Macintoshes with a great amount of CPU memory capacity. This is of vital importance because the microcomputer will probably operate in Windows, multimedia, and network environments that demand a lot of memory. Besides memory capacity, the speed of the CPU is important, especially if the machine is to be used for remote access. The major criteria that should be taken into consideration in selecting CD-ROM drives should include reliability, price, manufacturer or vendor's technical support, security, expandability, price, and audio playback capability. Safeguards such as built-in automatic laser read head cleaners, sealed casing, and doors to cover openings are of vital importance. Most of these requirements are met in products of major CD-ROM manufacturers, including NEC, Toshiba, Sony, and Hitachi. Reliability, especially the ability to withstand extremes of temperature, humidity, shock, vibration, and contamination, should be one of the major criteria in selecting CD-ROM drives, as many developing countries face harsh climatic and environmental conditions. The choice of CD-ROM drives for developing countries may pose a challenge. Compton reported that "finding manufacturers to build reliable drives was a headache as was navigating the complex maze of import-export regulations."^[40] The speed criterion is particularly important in selecting CD-ROM drives. As noted above, one of the criticisms of CD-ROMs is that they are slow. If speed is very crucial in the application of CD-ROM in an organization, then fast drives may be used. In selecting CD-ROM drives, serious consideration should be given to the DVD option. DVD drives can read discs containing at least 4.7 gigabytes of data, more than seven times as much as today's CDs. Dual-sided discs would double data capacity. If the information system intends to provide access to CD-ROM databases over a network, CD-NET servers such as the Meridian Data CD-NET server may be used. It is desirable to select a CD-NET server that has substantial expandability and compatibility with most PC local area networks such as Novel, Banyan, Microsoft, and IBM. Regarding the selection of printers, dot matrix and laser jet printers are suitable because of their low cost, simple operation, high speed, and durability. Nonetheless, dot matrix printers produce a high-pitched noise and hence are not the most suitable for public services. Jet printers are quieter, but they cost more and have special requirements. Laser jet printers, though also relatively expensive, are the most suitable for full-image article printing. For routine printing work in CD-ROM systems, dot matrix printers may be the most appropriate because they are less expensive, reasonably durable, and do not have special requirements.

Special hardware may be needed in installing a full-text image database as well as multimedia products. Jukeboxes may be needed for accessing hundreds of discs easily without having to change the numerous discs manually. To provide remote access, remote searching and printing hardware and software may be required. Information

systems in developing nations cannot do much in selecting the CD-ROM retrieval systems, however, until a common CD-ROM search interface emerges, libraries and information centers may circumvent the problem of the lack of a common CD-ROM interface by subscribing to CD-ROM products from the same producer, especially the systems that are user-friendly and well known, such as Wilsondisc and Silverplatter. Moreover, information professionals in developing nations may provide feedback to CD-ROM manufacturers. Such feedback would be used to enhance information retrieval systems in future editions. It is important to select appropriate CD-ROM network software. Whatever system is selected, it should be easy to install and use, allow simultaneous multiple access to the shared CD-ROM-related resources, include E-mail, and support Windows and DOS as clients. Furthermore, the software should also have a good facility of expandability, and should be able to accommodate additional drives to support larger and more diverse sets of information and multiple systems for the network. Finally, it should work well with most popular computer local area networks. Regarding remote access to CD-ROM databases, information systems should opt for reputable communication software packages such as PROCOM or Norton PC Anywhere, and CROSSTALK.

Bearing in mind the needs of the actual and potential users as well as the actual use of the existing resources in various formats, appropriate databases could be selected for acquisition. The major consideration in selecting CD-ROM databases should include: relevance to user needs in terms of subject, geography, language, type of literature, and period coverage. The existence and availability of alternative sources of information at the library, institutional, national, regional, and international levels should also be taken in account, since those resources may be accessed through cooperative resource-sharing programs. Frequency of use of printed sources or online database versions is a useful criterion in selecting CD-ROM databases. Other factors that should be taken into consideration include vendor reliability, licensing and lease terms, alternative price arrangements, and user interface. While subject-specific databases that are not adequately covered in the core databases available in the library information system may be acquired, high usage of such databases cannot be expected. Information systems in developing nations may therefore concentrate on acquiring and maintaining a core collection of heavily used databases. Subject-specific databases may be accessed in other formats or in other institutions through resource-sharing activities. Institutions in developing nations may seriously consider acquiring major CD-ROM databases that have extensive coverage of developing countries. Such databases include CABI, TROPAG, POPLINE, AGRIS, and LILACS. Library information systems in developing countries should also endeavor to produce CD-ROM databases of their local sources of information, especially

unconventional literature such as official publications and unpublished reports.

Although the installation of CD-ROMs is not difficult, information professionals who are not computer-literate may find it perplexing; however, local resources from computer departments in the parent organization or vendors could install CD-ROM systems. It is no longer prudent to fly in consultants from developed countries to install CD-ROMs or to offer initial training.^[41] Having installed the CD-ROM system, initial training may be conducted for the staff who will be directly involved in operating the system. Training should be preferably conducted on-site so that many staff members benefit from it. If training is provided outside the organization, then a person should be trained to train his colleagues. Depending on the level of the trainees, the training program content may include microcomputer basics, hardware, software, MS-DOS, MS-Windows, WordPerfect, installation of CD-ROM databases, troubleshooting, information retrieval, and information marketing.^[38] At the University of Botswana, the CD-ROM training program consisted of the availability and content of CD-ROM databases within the University of Botswana library, bibliographical control of CD-ROM and the CD-ROM marketplace, how to start up CD-ROM, a few search technique basics, and how to find information and get online help. There were also plans to cover operating systems and environments, PC management, desktop publishing, and computerized communications and online searching.^[42] Once the CD-ROM system is operational, it should be publicized and user training activities in groups or individually should be organized; online tutorials, library Web pages, and print materials should be utilized. Apart from utilizing the CD-ROM technology for information retrieval and technical operations, CD-ROM could be utilized to provide value-added services such as current awareness and selective dissemination of information to policy and decision makers, researchers, professionals, and other types of users.

In addition to systems-related user training and publicity concerns, complaints have been aired about document un-availability and delays in interlibrary loan and document delivery as well as staffing. Users in developing countries identify relevant sources of information through searching CD-ROM bibliographic databases only to be frustrated by the fact that their library does not own the actual physical documents. Efforts to obtain such documents through interlibrary loan are hampered by delays due to communications problems as well as personnel constraints.^[43] Library staff would also be adversely affected by the introduction of a CD-ROM service. Not only would they have to deal with the user frustrations mentioned above, but they would also have to study the system and documentation and to practice CD-ROM database searching, which may entail learning different search retrieval systems. They would also have to conduct user

education, offer assistance in information retrieval, and attend to clerical and technical duties, such as fixing printers. Library services and resources have been equally affected by the introduction of CD-ROM systems. Apart from user education, assistance, and interlibrary loan, there may be a significant decline in the use of mediated international online systems. Also, the space problem, which is a perennial problem in many information systems in developing nations, may be exacerbated. The use of print indexes may decline, and consequently cancellation of subscriptions to print indexes and journals in the case of full-text or image databases may follow the introduction of a CD-ROM service.

A number of strategies may be implemented to alleviate some of the major problems arising from the implementation of CD-ROM projects. At the planning stage, some budget provision should be made available to cope with projected increasing demand for more and different types of databases, CD-ROM stations, network costs, jukeboxes, and CD-NET servers. As for system maintenance, staff with sound information technology background, competence, and experience should be recruited. Alternative, a staff member with interest and aptitude in IT should be made responsible and be trained in troubleshooting. Other issues, such as user-friendliness and system slowness, may be addressed at the stage of system selection by selecting fast CPUs and CD-ROM drives. As for document availability and delivery, efforts should be made to subscribe to highly used journals that are indexed in a CD-ROM index. If funds allow, full-text or image databases should be purchased. In the case of projects funded by donor agencies, some budget for interlibrary loan or document delivery should be allocated. Subscription to CD-ROM databases that carry substantive abstracts such as *ABI-INFORM* may be a useful alternative to information systems in developing countries, which may never have access to the physical documents. Regarding staffing problems, many libraries and information systems may not be able to provide additional staff in response to the increasing workload due to the introduction of a CD-ROM service. The existing staff may try to cope if all concerned staff would acquire competencies and proficiencies in CD-ROM searching. Staff members may also be transferred from other library departments to CD-ROM service departments.

Since its advent in the library world a decade ago, CD-ROM has to date proven itself as one of the most appropriate technologies for information storage, processing, and retrieval, and for the dissemination of information in developing nations. Library information systems should therefore exploit the CD-ROM technology in developing appropriate relevant and indigenous CD-ROM databases; however, CD-ROM does not provide the best access to information, which is through network resources such as the Internet and intranet. Library information systems in developing nations should therefore make the best use of

CD-ROMs and at the same time they should strive to provide access to network resources to complement CD-ROM resources.^[43]

Access to Network Resources

The international community and national governments have recognized the imperative of resource sharing through information networks for a long time. It has been argued that the optimal and cost-effective use of the limited resources could be achieved through resource sharing and cooperation within the context of information networks. UNESCO has spearheaded efforts to develop cooperative programs and information networks in developing nations. Recommendation 21 of the UNISIST study report proposes that UNISIST should, among other things, propose guidelines for establishing and managing information networks and help to design a few pilot projects to assess different ways of linking developing countries with UNISIST.^[45] One of the major programs of GIP (General Information Program of UNESCO) is the improvement of access to information through the use of modern technologies, standardization, and interconnection of information systems. One of the subprograms is on the exchange and flow of information through regional and international cooperation among member states and within the organizations of the U.N. system.^[46] Other U.N. agencies, especially the U.N. Atomic Energy Agency through its INIS project, the FAO through its AGRIS program, the WHO, and the UNFPA through its support to POPIN, have contributed to the development of information networks in developing nations. These organizations have developed global information networks with regional, national, institutional, or sectoral nodes. The IDRC through the DEVSIS programs as well as through cooperation with such other donor organizations as UNDP, UNFPA, and UNHCR, has greatly assisted developing nations in developing information networks.

The objectives of implementing information networks in developing nations include the following, as stated in the objectives of the Pan Africa Documentation Information System:

1. Identifying and collecting information resources and creating an efficient system for the utilization of information.
2. Promoting information exchange.
3. Establishing a system that would ensure access to both published and unpublished documents.
4. Providing assistance to member institutions to strengthen their information infrastructures so that they would be able to participate fully in the system by contributing as well as deriving benefits from it. These would include regional, subregional, or sectoral participating centers.

5. Establishing links (systems interconnection) with international information networks, databases, and information and documentation units.
6. Utilizing the most recent technology of data transmission, including telecommunication satellites.
7. Organizing the necessary training programs for users.
8. Establishing technical procedures and standards to ensure the system's compatibility with existing national and international information systems to facilitate information transfer and exchange between them.^[47]

The main functions of information networks have been to explore the needs of information users, to define the field to be covered, to identify all information available on the field, to choose methods that allow for the transfer of information between information centers (standards and systems interconnection), to supply information and documents to users by compiling and publishing directories, union lists, newsletters, and similar publications, to provide technical assistance, and to organize training workshops for information specialists and users. Information technology has been utilized in enhancing most of the functions of information networks. It has been used in identifying and creating information resources through the use of indigenous databases, online and CD-ROM databases, the development and use of common standards and information-processing tools, information dissemination, and promotion of information exchange. Information technology has also been utilized in providing training.

The 1980s and 1990s have witnessed the development of and access to computer networks in developing nations. A few examples of such networks are: GULFNET, Internet,^[48] Fidonet,^[49] and BITNIS,^[48] a network arising between the University of Chile and the National Library of Medicine that permits the consultation of the MEDLARS database via E-mail. In the Muslim world, the International Organization of Islamic States is in the process of developing a network on Islam (OICIS-NET) that will also serve as a gateway to the Internet.^[50]

The World Bank and UNDP have also been involved in promoting the development of computer networks in developing countries. The World Bank, in collaboration with UNDP, OSS/UNITAR, and USAID/WRI-NRICG has developed AFRICA-EIS, an E-mail service provided by the program on environmental information systems in sub-Saharan Africa hosted at the Environmentally Sustainable Development Division (AFTES) of the Africa Technical Department of the World Bank. The objective of AFRICA-EIS, which is open to any interested parties, is to provide a forum for discussion and especially to promote the use of geographical information systems (GIS) and spatial information on environmental issues as a support tool for decision making for natural resource management in sub-Saharan Africa. AFRICA-EIS keeps an archive and an index of issues relevant to GIS issues and

a list of EIS newsletters of the program on environment information systems in sub-Saharan Africa. Through this network, a user can contribute to a conference and request a document. Many African countries have already participated in the network in sharing information. These include Benin, Botswana, Burkina Faso, Ivory Coast, the Gambia, Ghana, Kenya, Lesotho, Madagascar, Mali, Nigeria, Senegal, Mauritania, Mozambique, South Africa, Tanzania, Uganda, Zambia, and Zimbabwe.^[51] The UNDP has also recently launched a network of immense value to developing nations. The Sustainable Human Development Network Program (SDNP), a computer-mediated communication project of the UNDP, addresses issues of information flow by fostering information sharing within developing countries, empowering users, and helping decision makers on issues related to sustainable human development. The project was launched in 1992 with twelve countries in Africa, Asia, and Latin America. To date some twenty countries are or will shortly be in operation with SDNPs. These countries include Angola, Chad, Indonesia, Pakistan, Nicaragua, Honduras, Bolivia, Cameroon, Lebanon, Morocco, Tunisia, Korea, Colombia, Guatemala, Chile, Mexico, India, and Costa Rica.^[52]

Another interesting development in networking is the development of networks through the cooperation of institutions in both the South and the North. A good example of such networks is the PANGIS (Pan-African Network for a Geological Information System) network. The PANGIS network was initiated by ASGA (Association of African Geological Services), with the technical support of CIFEG (International Center for Training and Exchanges in Geology). The network is currently supported by UNESCO, cooperation agencies of French-speaking countries (ACCT and BIET), and the French ministries of industry, foreign affairs, and research and technology. PANGIS uses formats and procedures compatible with the common communication format and exchange modules compatible with PADIS or AGRIS methodologies. The centers were initially equipped with 386 microcomputers and used the CDS/ISIS 2.32 software. A quarterly bibliographic bulletin and a CD-ROM database are produced by the PANGIS network.^[53]

Besides information networks that have been established through international cooperation, some developing nations have developed their own information networks. A good example of such a network is Gulfnet, which was established by the Saudi government in 1985. It is a computer network of academic and research institutions in the Arab world—a store and forward network similar to BITNET. Gulfnet has two major goals: to provide an infrastructure for the exchange of data, information, and messages between scientists and researchers in the Arab Gulf countries as well as to promote informal cooperation and thus promote cooperation in research projects. The Gulfnet Academic Network consists of fourteen institutions: eight Saudi universities, KACST, King Faisal

Specialist Hospital and Research Center, Cooperation Council for the Arab States of the Gulf, Ministry of Health, Islamic Research and Training Institute, Kuwaiti Institute for Scientific Research, Kuwait University, and IBM Kuwait Scientific Center. Gulfnet provides the following information services to its participating centers: accessing international databanks, providing document delivery, maintaining a union list of periodicals held by participating centers, and providing access to a bibliographic and terminology databank and the library online catalog. Other services provided through the Gulfnet communication networks include interactive messaging, file transfer, E-mail, a user directory, access to databases, conference systems, and CHAT, an organized way of providing E-mail and an answering service for answering reference queries. Gulfnet provides access to many computer and medical forums, as well as access to the KACST library information resources and databases such as the CICS DOBIS/LIBIS and dial-up or public data network access to over eighty international databases and eighty-four online CD-ROM databases.^[54]

In implementing information networks, library information systems have faced numerous problems. One of the critical management concerns that has adversely inhibited the effective implementation of information networks in developing countries concerns organizational structure and approach. Most cooperative information networks consist of coordinating units at global, regional, and national levels, which consists of participating centers at a lower hierarchical level. The problem with that kind of information network structure is that the coordinating unit seems to be benefiting more from the network than the participating nodes. Coordinating units tend to be better staffed, better provided with equipment, and alienated from the practical problems prevailing in regional or national participating centers. As a result, participating centers are indifferent or apathetic, since they do not see any tangible benefit from participating in the information networks that do not provide any material, financial, or personnel support. The initial enthusiasm of participating in the network wanes in the failure of regional information networks or their governments to provide the necessary support for effectively implementing information networks at the regional or national node. In order to tackle this problem, the approach should rather be from the bottom to the top. The regional, subregional, or national participating centers should be provided with financial, human, information, and other material resources. Another organizational structure issue related to the implementation of information networks in developing nations is the fact that oftentimes inappropriate institutions are designated as national coordinating centers due to political and other nomenclature factors.

Regarding technical operations of the network, standardization and compatibility of hardware and software systems as well as information-handling tools and

methodologies pose the most significant challenges. It is thus essential that information networks examine existing standards and apply totally or partially standards that are compatible with international standards, such as UNESCO, CCF, UNIMARC, ISBDS, and AACR II. Since these standards do not adequately cover developing nations, standards should be modified to meet local requirements. Reclassification of geographical regions may be necessary. Likewise, manuals should be made as simple, self-explanatory, and accessible as possible.

Another major technical operational constraint faced by information networks is inadequate telecommunications systems. Telephone lines are inadequate, slow, and unreliable. Dial-up services are often very slow, and leased circuits are too expensive. Circuits and bandwidth are often overloaded and the network links may be saturated. A number of alternative options such as the use of microwave networks, installation of X-25, use of packet radio, use of orbiting satellites, or Fidonet technology and the use of CD-ROMs should be explored. Last but not least is the problem of establishing and developing information networks in developing countries because of the widespread lack of awareness of the existence and potential of information networks, and consequently their underutilization. Publicity and user training should therefore be essential components in the planning and implementation of information networks.

Internet Access

In addition to cooperative international and regional information networks, many information systems in developing nations are already connected to the Internet. Many library information systems started using the Internet in the early 1990s. In Latin America and the Caribbean, for example, 1994 marked the year of consolidation or integration of numerous national networks into the global Internet. However, some institutions, such as SAICYT (Sistema Automatiza Informacion Cientifica y Tecnologica, or Scientific and Technological Information Automated System), established connections to the Internet through the JVN Cnet (John Von Newman Computer Network) of Princeton University by the end of 1991. By May 1993, SAICYT was completely based upon the TCP/IP protocol.^[48] In Africa, South Africa was connected to the Internet in 1991, although efforts to establish Internet connection started in 1989.^[56] In the Middle East, some countries, such as Egypt, have had limited Internet access since 1993, whereas the Arabian Gulf countries such as Kuwait and the United Arab Emirates established an Internet connection in 1994/1995. A number of countries in the Asia Pacific region, such as Malaysia, Indonesia, and Taiwan, established an Internet connection in the early 1990s.

There is a wide range of potential benefits of using the Internet in developing countries. The global network may

play a crucial role in tackling the book famine experienced by many libraries in developing nations. Westhuizen argues that the electronic library enables access to electronic journals and books via computer networks through the Internet and by telephone modem.^[56] On the other hand, it has been recognized that due to infrastructural problems, many information systems have not taken advantage of IT, including the Internet. In fact, it has been argued that the Internet may exacerbate underdevelopment. Sanchez-Vegas contends that if accessibility obstacles—funding, ownership, and costs—are not adequately addressed and resolved, then only the elite (within and among countries) will benefit from this immensely powerful information superhighway.^[55] However, it is encouraging to note that in spite of the many problems related to Internet access in developing countries, the Internet has been used for a wide range of purposes. Through Internet remote log-in, some libraries have had access to the most important data and knowledge banks. Ainsworth and Levinson underscored the use of the Internet to solve problems of access to databases and the wealth of information available through the link of information systems. Levinson contends that the Internet offers many national and international library catalogs with strong Latin American collections and that they frequently help with reference interlibrary loan, and collection development. Having established a connection to remote online catalogs, libraries can verify library holdings for interlibrary loan (ILL)/document delivery purposes and the selection of reference sources.^[57,58] Through Telenet connection to bibliographic, referral, numeric, full-text, and image databases, information systems can retrieve and obtain valuable information that can be used for research, reference, document delivery, current awareness, and acquisition purposes.

Library information systems in developing nations can use the FTP (file transfer protocol) of the Internet to download files of documents for ILL or document delivery, current awareness, or the building of an electronic sources reference collection. For instance, the veterinary science library at the University of Pretoria in South Africa uses FTP to build its electronic sources collection, downloading relevant animal health information such as descriptions of various animal breeds onto disk for its students. Westhuizen indicates that through FTP they often find information difficult to obtain or unavailable in the more conventional publication forms.^[56] Probably the most viable application of Internet in developing countries has been E-mail communication. Relevant Internet lists have been used for exchanging relevant and topical information or requesting hard-to-come-by articles. In Africa, for example, many libraries have an E-mail connection. These include the medical library of the University of Zambia, the veterinary library of the University of Zimbabwe, the veterinary faculty of the University of Eduardo Mondlane, Mozambique, the International Livestock Research for

Animal Diseases (ILRAD) now International Livestock Research Institute (ILRI) library in Nairobi, Kenya, and Makerere University in Uganda.

One of the interesting recent developments in Africa is the project of the "African virtual university." The university is a World Bank pilot project that is linking selected African universities to European and U.S. institutions. Recognizing that most libraries are empty shelves and that broken science facilities litter most of the laboratories, the World Bank believes that with planning and commitment, these dilapidated universities could make use of the life-line from cyberspace. As a first step, the World Bank has established a Web site for the new university. It is also encouraging private information technology bodies to provide Internet links to universities and research institutions in sub-Saharan Africa. During the first phase of the \$1.2 million project, Makerere (Uganda), Hailie Sellassie (Ethiopia), Dar es Salaam (Tanzania), Nairobi, Moi (Kenya), Legon, Kumasi (Ghana), and Zimbabwe universities will form an examination faculty for the African virtual university, while the University College, Salway, and the New Jersey Institute of Science will provide lectures and course materials.^[59]

The Internet's conference features have also been exploited for information dissemination. Westhuisen gives a good example of such a conference on animal health. The WINROCK International Livestock Conference held in 1993 had participants in Colombia, Peru, Bolivia, India, and other developing countries as well as in the United States and Europe. The conference continued for several months, with keynote papers being commissioned and contributions being made by a wide range of participants without incurring travel costs. Also, published conference proceedings can be accessed through electronic conference.^[56]

Although there is a wide recognition of the advantages of using the Internet, many developing nations have not exploited the potential of the network due to a number of complex problems. Two major interrelated bottlenecks have hampered access to the Internet resources: lack of reliable good data communications systems and the relatively prohibitive communications cost. Citing the state of communications in Latin America, Cubezas^[48] pointed out the lack of a dependable communication system, while Lawrie, in reference to the situation in Africa, identified poor telecommunications infrastructure as well as prohibitive prices as some of the major factors inhibiting access to the Internet.^[60] Kamaruddin points to the lack of both high-speed data communications facilities, and a direct link to the Internet as two of the obstacles that would hamper Islamic nations from fully benefiting from the services of the OICIS-Net (Organization of Islamic Countries Information Systems Network) project.^[50]

Other problems related to poor communication systems include rigid, time-consuming, and difficult log-on procedures and an overloaded or saturated bandwidth. The

constraints pertinent to prohibitive costs encompass expensive leased circuits and other prohibitive prices. Other issues that inhibit the effective utilization of Internet resources in developing nations include weaknesses of library collections and hence the problems of identifying and obtaining relevant, up-to-date sources, a lack of understanding of the strategic value of information, and easy access to undesirable sources, such as pornography and seditious literature. Kamaruddin claims that OICIS-Net would ensure that its users would be protected to the extent possible from some of the difficulties that have emerged in the Internet, such as an overload of information, a lack of security, and the tendency to use the network to exchange undesirable information.^[50] Some developing nations enact regulations and other control measures that inhibit or limit access to the Internet. Referring to South Africa, Lawrie points out that Internet connection was delayed in South Africa mainly because of telecom regulations that prevented any Internet activity.^[60] In order to alleviate the above problems, some developing countries have adopted a number of options, such as using store and forward E-mail networks such as Bitnet and Fidonet or dial-up link until the time when they would have UUCP or TCP/IP link. Research and academic libraries in the Arabian Gulf region, for example, have been using Gulfnet/Bitnet for E-mail communication, however, such E-mail networks have basic limitations since they are not interactive. Interactive Internet tools such as Gopher, WWW, or WAIS are not available at Bitnet/Gulfnet-only sites. South Africa also used a dial-up Bitnet telelink Fidonet mailing system from 1988 until 1990, when it got a dial-up UUCP link. For institutions that can afford it, the best approach would be to install a high-capacity satellite to enhance international links to the Internet. To tackle the problem of high communication costs, libraries should negotiate with telecommunication companies for fair costs. In order to provide access to indigenous literature, some information systems have developed local databases and made them accessible through networks. The following entry discusses the development and access to indigenous databases.

Development and Access to Local Databases

One of the major shortcomings of IT-based information sources in developing countries is inadequate coverage of information on developing countries. To address this problem, efforts have been made since the 1970s to develop local databases. Highlighting this problem in the foreword of the document *International Cooperative Information Systems*, IDRC-156e, IDRC contends that developing countries need first of all to build mechanisms so that the information that they generate themselves can be retrieved when it is needed for development purposes.^[4] IDRC has therefore been actively involved in assisting developing nations build databases on and in developing countries

that include considerable indigenous literature. In Africa, IDRC has significantly contributed to the development of the bibliographic and referral databases of the Pan African Development Information System (PADIS), the PIDSA (Population Information and Documentation System for Africa), and ILICA (International Livestock Information Center for Africa).

UNESCO has also been at the forefront in assisting developing nations plan and develop national bibliographic agencies and services through the provision of consultancy, equipment, software packages, and training. Examples of UNESCO participation in developing databases in developing nations abound. In Latin America, UNESCO has been instrumental in developing CRESALC—a database of UNESCO's Regional Center for Higher Education in Latin America and the Caribbean, covering Santiago, Chile, Port of Spain, Trinidad, and Caracas, Venezuela. Other U.N. agencies have participated in developing databases, including FAO, which has developed AGRINTER, a regional database located in Costa Rica covering Latin America and the Caribbean contributions to the worldwide database AGRIS; WHO, which has contributed to the development of the LILACS (Literatura de Latinamerica Sobre Ciencias de la Salud) database produced on CD-ROM in Sao Paulo, Brazil by BIREME, the Latin America Center for Information on Health; and the U.N. Environmental Program, which has developed PNUMA, which has regional offices in Mexico City and Kingston, Jamaica.^[61] Besides international organizations, some national institutions have developed local databases. In Saudi Arabia, KACST has developed a number of databases on Saudi Arabia. These include: science and technology database (English), Arabic science and technology bibliographic database (Arabic), manpower database, union list of serials database, current awareness database, science and technology terminology databank (BASM), online library catalog, research project data base, and project review database.^[62]

The rationale for the developing local databases has been to improve access to locally produced information for development. Such information would be useful to individuals and institutions in developing nations as well as those in the North, which are interested in information on or in developing countries. They would not only serve as selection tools, but would also enable users identify the existence and availability of relevant information. Most databases developed in developing nations have been mission-oriented, with the purpose of identifying and delivering information that can be useful in research and development planning and decision making, hence they are concerned not only with scientific and technical information that may be important in decision making, but also with economic, social, and legislative information. In their endeavor to develop indigenous databases, many information systems in developing nations have, however, encountered a number of bottlenecks. Most of the major

problems discussed earlier such as the lack of qualified and experienced staff, budgetary constraints, lack of a reading, documentation, and information culture and hence the underutilization of information systems, and language barriers have all hampered the effective development and use of local databases.

In addition to these problems, issues pertinent to information processing have also posed serious problems. The international information-processing standards, codes, rules, and guidelines do not always adequately meet the requirements of developing nations. Such information-processing tools as the *Anglo-American Cataloging Rules*, *UNISIST Reference Manual for Machine Readable Bibliographic Description*, *UNESCO Common Communication Format (CCF)*, and MARC and UNIMARC formats need to be modified to cater to the requirements of developing nations. This explains why many developing countries have developed their own national MARC formats formats.^[62] Indonesia has developed SINGMARC, South Africa SAMARC, Taiwan CHINESE MARC, and Thailand THAIMARC. In order to overcome problems posed by information-processing tools such as guidelines to bibliographic descriptions and thesauri, many information systems have developed their own guidelines. For example, PADIS and POPIN-Africa have developed the *PADIS Manual for Document Analysis and the POPIN-Africa Guidelines for Bibliographic Description and Analysis of Population and Family Planning*, respectively. Since the preparation of information-processing tools is time-consuming, it may not be wise to expend a lot of effort, time, and human and material resources in developing tools for an individual information system. For example, the development of comprehensive information tools by POPIN-Africa based on the PADIS manual was an unnecessary duplication of efforts. Information-processing tools developed by international or regional information systems should be adopted and tailored to the specific subject or geographical requirements of an information system.

Menou contends that the barrier to the exchange of bibliographic information created by incompatibility among formats was noted from the inception of UNESCO'S UNISIST program, which led to the proliferation of standard formats, giving birth to four groups of formats, somewhat similar yet antagonistic, that were supposed to overcome this barrier. Those geared to universal bibliographic control are best represented by UNIMARC, but such formats are relatively complicated and not very suitable for the management of databases in small, specialized documentation centers. The second group of formats derived from the UNISIST reference manual is more readily usable for the design of specialized national databases. Most international information systems are in line with the UNISIST manual (e.g., RESA-DOC and AGRIS); however, they can be regarded as a third group, as they have to introduce specific features according to their particular types of operation, which do not

necessarily correspond to the requirements of national databases, as well as to changes in the international systems. The last group, the common communication format, has intrinsic complications, and these formats are aligned on the basic organization of data elements found in the first group. Menou concluded that there is no format able to respond to all the constraints.^[64]

Thesauri pose significant problems. Major international thesauri do not adequately cover developing nations in terms of geographical and semantic scope. This shortcoming may be rectified if information systems in developing nations pointed out these weaknesses to the institutions responsible for building and managing thesauri. In order to ensure that different geographical regions and cultures are adequately covered, the organizations responsible for developing thesauri should include representatives from the different geographical regions. For example, the U.N. High Commission for Refugees included members from Africa, Asia, Europe, and Latin America in the International Refugee Terminology Thesaurus Working Group in 1988, when they were involved in compiling the International Refugee Multilingual Thesaurus. It is also important to develop multilingual information-processing tools for developing nations, since different languages are used in the Third World (e.g., English, Spanish, and French). The language barrier is obvious in information-processing formats as well as in information-processing guidelines and thesauri. Fortunately, concerted efforts to address these issues are under way. The Arab world, for example, has been striving toward developing Arabic MARC formats and "Arabizing" other information-processing tools and systems that are crucial for the development of local databases.

Interlibrary Loan and Document Delivery

Access to relevant references identified through searching local databases, CD-ROM, online, and other electronic network resources may be frustrating because the actual documents are not locally available. Many information systems have tried to solve the problems of document unavailability through ILL and document delivery. Cornish contends that CD-ROM stimulates a demand that cannot be satisfied by making the reader aware through extensive bibliographic data of what is not available.^[65] In view of the limited resources available in developing countries, ILL, document delivery, and cooperative acquisition have been recognized as vital possible solutions to the problem of collection deficiencies and document unavailability.

A wide variety of IT has been employed in ILL and document delivery, ranging from rudimentary equipment such as photocopiers to computer networks. Photocopiers have been used to provide current awareness and document delivery services, as was the case of the East Africa Literature Service and the Tanzania Literature Service.

These two services provided photocopies of tables of contents to scientists who selected relevant articles. Photocopies of the selected articles were delivered to the scientists by mail. Telex has also been used in many developing countries, mainly for requesting documents; delivery is through the mail. Requests for ILL are also often submitted by phone. Fax machines are used both for transmission of requests as well as for document delivery. E-mail has also been utilized for submitting requests. In the Arabian Gulf, E-mail requests are submitted through Gulfnet, and documents are sent by mail or through the FTP facility of Gulfnet. Other libraries in developing nations, such as the KFUPM library in Saudi Arabia, submit their requests to the British Library Lending Division through ARTTel (automated retrieval telephone). Besides utilizing IT in transmitting and receiving ILL requests, IT has been used in ILL database management.

Information technology has also played a vital role in developing and enhancing access to location tools such as online catalogs and union lists in machine-readable formats such as magnetic tapes or CD-ROMs. Guerrero points out that IT has improved availability for some of the libraries by creating union catalogs essential for identifying and locating documents. In Latin America, for example, LIBRANUM, a union catalog on CD-ROM, covers holdings in 164 departments of the National University of Mexico and included 500,000 records in 1995. The university union catalog of serial holdings also includes sixty-two other higher education institutions and research centers in the country. The National Library of Venezuela has an online union catalog containing more than 900,000 records, which contains information on monographic and serial holdings.^[66]

Notwithstanding some significant achievements in utilizing information technology to enhance ILL and document delivery services, numerous barriers have impeded the optimal exploitation of IT in interlending and document delivery. Lack of adequate financial, human, and material resources, poor information policies, and inadequate information infrastructure are some of the major problems. Probably the most important problem is the nonexistence or lack of availability of adequate location tools. Ferguson suggests that librarians may overcome this problem through the development of national databases of locally published materials, and cites the example of the National Library of Jamaica whereby the development of a national database has contributed to the growth of ILL activity. Ferguson also advocates participation in sectoral information systems such as INFOTERRA, LILACS, ECLAC, and AMBIONET.^[67] Cornish recommends that union catalogs that take into account uniformity of style, cataloging, practice, and formats should be combined. Since union catalogs are difficult and time-consuming to compile, Cornish suggests an alternative strategy of compiling directories of strengths of collections.^[68]

An equally important issue that librarians have faced in implementing IT is the increasing demand for ILL resulting from identifying citations through searching IT-based systems for which actual documents are not owned by the local library. Barr points out this problem as follows: "It is extremely frustrating if the references are obtained but the documents to which they refer are not available." To overcome this frustration, Barr recommends that information systems in developing nations should try to obtain special funds for document delivery; measures should be taken to combine reference and document delivery of core heavily used journals; and the existing research libraries should be consolidated.^[69] Kanamugire suggests that this problem may be alleviated through the production of CD-ROM products with substantive abstracts, since many libraries and information centers in developing nations do not have easy access to efficient ILL or document supply systems, and further suggests that donor agencies should allocate a budget for purchasing photocopies of references identified through CD-ROM searching.^[70] In another article on the impact of CD-ROM on ILLs, Kanamugire concludes that libraries that decide to offer a CD-ROM bibliographic database search service should anticipate an increase in ILL requests and be ready to respond accordingly to the impact of CD-ROM database searching through providing more human, financial, and information resources. He also suggests that libraries offering CD-ROM index services should seriously contemplate acquiring these journals not only in hard copy, but also in CD-ROM image and microform formats.^[43] Keylard suggests that information systems in developing nations use the facilities of the many CD-ROM producers that offer document delivery for references included in their databases.^[38]

Many problems inhibiting document delivery and ILL in developing countries are caused by the existing poor information infrastructure. Referring to the situation in Latin America, Guerrero points out that insufficient or unreliable postal and other services lead to delays in document delivery or loss of documents.^[66] To overcome the problems posed by inadequate postal services, a number of options have been advanced, but many of them are not viable. Cornish suggests that telefax could be used for requesting documents and that the requested documents could be received by normal mail since transmission of documents by fax would be prohibitively costly. This approach has been adopted by Barbados and Trinidad.^[68] Similarly, Ochs recommends the use of telefax because it is efficient, cost-effective, and provides rapid delivery of documents. She further points out that some telefax machines have a feature for delayed sending, taking advantage of off-peak phone rates, and suggests that in purchasing a telefax machine, one should look for as much memory as possible in order to send a large number of pages on off-peak hours.^[71] Phone lines have also been useful in requesting ILL documents as well as for

receiving documents. However, they are also expensive and unreliable, and because of a lot noise and vibration, they are of low quality. Poor phone lines may lead to a distortion of image documents. Also, fax modems used for transmitting messages have to step down to lower speeds due to poor phone lines. This results in an increased communications cost and poor quality. In the short term, little can be done to improve the quality or cost of phone lines, but in the long run, librarians should continue supporting efforts to improve telecommunications infrastructure and to decrease phone charges. In addition to fax and phone media, another medium that could be used in transmitting and receiving ILL and document delivery requests are computer-based communications systems. However, many information systems have not used electronic media because online delivery is prohibitively expensive and also because of the lack of adequate data communications networks.

In addition to problems pertinent to tools of identification, document unavailability, and infrastructural problems, other key ILL/document delivery obstacles experienced by information systems in implementing IT projects include: behavioral problems, lack of equipment, secrecy and confidentiality, financial constraints, and poor collections. Oftentimes there is no budget for ILL/document delivery activities. Even when there is a budget, hard currency to pay for ILL documents is not easily available. To solve this problem, there should be a fund for document delivery. The British Council has helped many developing countries in obtaining the British Library Document Supply Center photocopy coupons by accepting payment for the coupons in local currency.

Another problem related to finance is the lack of equipment, especially photocopiers. There are insufficient and unsatisfactory photocopying machines, and even if machines are available, shortages of paper and other materials, the unavailability of spare parts, poor servicing arrangements, and frequent power failures adversely affect photocopy services in developing nations.^[69] In order to solve this problem, equipment, especially photocopiers, should be one of the major components in the planning and implementation of IT projects. Also, there should be a budget for paper, toner, and other supplies. Libraries and information systems should charge for photocopy services and use the money collected for purchasing new photocopiers, for buying supplies, and for meeting other photocopy recurrent costs. Since it may be difficult in some libraries to afford a one-time purchase of a photocopier, information systems should negotiate with vendors to procure photocopiers on loan or for payment in installments. Another option of providing a photocopy service when the institution cannot afford purchasing a photocopier would be contracting a photocopier vendor/dealer to provide photocopy service in or near the library. Under such an arrangement libraries may get some discount and some other preferential benefits. The last, but

not least, major barrier to ILL/document delivery in developing nations is behavioral or attitudinal. Graham contends that information professionals are unwilling to become too involved in interlending because of fears of loss, damage, financial commitment, and inconvenience to library's home clientele.^[65] Guerero argues that a major drawback in ILL/document delivery in Latin America is that a few of the larger libraries will have to deal with the great bulk of the demand, which will conflict with the needs of their own users.^[66]

Although interlending has been advanced as a possible solution to the problems of inadequate collections, there are a number of obstacles that limit the effectiveness of ILL in developing nations. Mills contends that borrowing outside their own region is beyond the budgets of many libraries.^[72] Allen argues that ILL is not a practical method, or even generally a legal method, for the provision of textbook material to undergraduate students. The volume of material in demand would be too large for lending libraries to handle, there would be numerous copyright hurdles to overcome, the time factor would be extremely difficult to manage, the physical format, durability, and usability of the copies so supplied would make them difficult for receiving libraries to handle, and the costs, at ruling rates of supply from the major supplying libraries, together with postal or electronic delivery charges, would almost certainly make them as expensive as purchase. He emphasized that the present ILL financial structures militate against its extensive use by developing country libraries and pessimistically concludes that the ability of librarians, however well motivated, to make any meaningful impact on the resources of developing country libraries through ILL is extremely limited.^[71] Many library information systems have therefore focused their efforts on strengthening collection development activities.

Collection Development

Collection development in developing countries is fraught with many difficulties, especially financial ones. Probably no other function of libraries is so adversely affected by the lack of financial resources as that of collection development. Without adequate funds in local as well as hard currency, many libraries have failed to develop or update their information resources. This problem is compounded by the ever-skyrocketing prices of journals and books. Woolston highlighted the problems of price, foreign exchange, lengthy bureaucratic procedures, and the lack of a domestic information industry. Woolston asserts that prices that appear reasonable in, say, the United Kingdom are astronomical in Bangladesh. Worse still, it has to be paid for in hard currency, which may be difficult to come by.^[74] Similarly, Kaungamno, referring to Tanzania's situation, stated that

Probably the most crucial problem facing librarians in Tanzania is the lack of foreign exchange. The local book

industry faces many difficulties, and the absolute dependence on imported books threatens the existence of libraries. Libraries cannot keep their book stocks up to date. The situation has been made worse by inflationary prices all over the world, and it is difficult to get a sufficient number of suitable books.^[75]

Allen clearly highlighted the problem of acquisitions in developing nations as follows:

The essential problem in the developing countries is that libraries do not have the funding to purchase the required resources in sufficient quantities from the developed world publishers. This problem is being exacerbated by the deteriorating economic situation in many developing countries, while the situation of political instability and even total collapse of civil authority in some countries, are only making an already pain situation intolerable. At a time when the librarians of major American universities are debating action to offset the escalating costs of publications, the ability of libraries in the developing countries to acquire even the most essential materials is threatening their operations with extinction.^[73]

Some of the problems of inadequacy of information sources may be solved by making better use of the substantial amount of unconventional literature in the social, natural, and physical sciences produced in developing countries. However, it is extremely difficult to identify the existence of and to acquire such literature because of poor bibliographic control. Unfortunately, unconventional literature is usually produced in limited quantities and stocks are consequently used up as they are produced. Nonetheless, there have been some positive developments in bibliographic control of gray literature over the past two decades. Some donor agencies, especially the IDRC through its DEVSIS programs, has rendered assistance in developing bibliographic databases and collections to some institutions in developing countries, including the University of the West Indies in Jamaica and the PADIS in Africa. Similarly, FAO and UNFPA through their AGRIS/CARIS and POPIN programs, respectively, have significantly contributed to bibliographic control of developing country unconventional literature.

In his study on resources acquisitions and the viability of university libraries in developing countries, Allen advances one viable suggestion that IFLA could implement.

That expert subject committees be established, or the advice of specialist subject associations to select limited numbers of up-to-date text books of recommended additional readings for the support of undergraduate studies in the major disciplines taught in a majority of universities in developing countries, and that negotiations then be undertaken with the publishers of such texts for the production of special editions/printings to be made available to university libraries in developing country libraries at, or near to marginal production costs.^[73]

It would demand considerable effort to convince the academic staff of university libraries in developing countries that the proposal is workable and does not imply intellectual imperialism, while publishers would also need to be persuaded that their commercial interest would not be harmed. Allen also advocated negotiations of a twin relationship between a specific library in a developing country with a specific library in a developed country. He points out that such an arrangement may do much to develop ongoing close relationships that are of cumulative value to both libraries in the partnership.

Libraries in developing nations should also take advantage of international programs that aim at addressing collection development problems. Such programs include the UNESCO coupon and twinning programs as well as the INASP project of the international Council of Scientific Unions (ICSU), which is supported by UNESCO. INASP is a cooperative network of donors and representatives of recipient institutions. It has three immediate objectives: to map, support, and strengthen existing programs involved in the distribution, local publication, exchange, and donation of books, journals, and related materials (e.g., maps and charts, audiovisual materials, software, and CD-ROM); to encourage and support new initiatives that will increase local publication and general access to quality scientific literature, and to identify methods that will permit the ongoing and sustainable exchange and distribution of scientific publications.^[74]

Since it is virtually impossible for developing country governments to allocate adequate budgets for the purchase of books and journals, information systems may also benefit from the numerous institutions involved in donation programs, such as funders who provide funding for other groups to use; donors that donate books for distribution in other countries; senders and suppliers that collect books from donor and send the materials to recipients in other countries, primarily libraries; and distributors—that is, organizations in or acting on behalf of a specific country that collect or solicit donations. At times the solicited donations are in response to requests from receiving libraries for specific titles. An example of such an organization is the Asia Foundation, which distributes an average of 1 million books and journals a year to over 8,000 libraries, schools, universities, research centers, and government agencies throughout the Asia-Pacific region. The British government through its Overseas Book Development Program has played a crucial role in this respect. The British Council also accepts payment in local currency for purchasing British Library photocopy service coupons, which are then used for ordering photocopies of articles or for borrowing books from the British Library Document Supply Center. Books for Africa procures and ships books to indigenous, nongovernmental partner organizations in recipient countries that receive and distribute books to libraries and schools. It handles 500,000 books a year. Ranfurly Library Service (RLS) sends over 700,000

books overseas every year in response to urgent requests. The CTA finances a donated books program through which 44,000 of its own publications as well as an additional 10,000 non-CTA books are distributed annually. The World Bank Volunteer Book Project (WBVS) receives donations of new and used books from schools, universities, libraries, medical schools, and publishers, and ships over 120,000 books annually to several developing countries. The U.S. Information Agency (USIA) sometimes donates collections on an occasional one-time basis. The USIA book programs division also conducts programs to promote the sale and distribution of American books overseas in close collaboration with the book export efforts of the American publishing industry. The books are eventually donated to foreign institutions.

Although some libraries and information centers have benefited from gifts and exchange and other resource-sharing activities, donations and gifts and exchange programs have been criticized on a number of grounds. First, libraries are supplied with materials that are not the most desirable. As a result some key subjects may not be adequately covered, and the collection may not be updated as donations are given on an occasional one-time basis. Mills summed up the problems associated with the reliance on donations for a significant proportion, sometimes the majority, of their book stock, and pointed out that such reliance may lead to collections that are not in keeping with the needs or objectives of their users, since donations depend on what the donors are able to offer. Consequently, collection gaps, unevenness in coverage of subjects, and outdated collections may occur.^[72]

Recently the concept of library twinning has been given special attention by IFLA. IFLA contends that twinning of libraries arises from the need to improve the practice of librarianship across national boundaries.^[77] Nancy John listed, among other things, the following factors as being relevant to information resource sharing: exchange of information about libraries; improved access to published information in both developed and less developed countries; information about new techniques for library management and new technologies for library programs to be made available more widely in developing countries; greater awareness by libraries in developed nations of the issues facing libraries in developing countries; regular international sharing of problems at the operational level; involvement of all levels of library staff in sharing information about their problems and common concerns; and a broader view of the library profession.^[78] Doyle contends that collection development seems to be the preeminent rationale for twinning arrangements with a library from another country and it leads to the acquisition of materials usually difficult or impossible to obtain using conventional methods. Moreover, twinning arrangements in resource sharing and through donation and exchange programs can help and improve delivery and collections.^[79]

To tackle the immense collection development problems, a combination of traditional and innovative methods should be adopted in the acquisition of library materials. Alumni may be requested to support the library, chairs may be established, and the library may be involved in fund raising and income-generating activities. Resource-sharing efforts through ILL or cooperative acquisition have failed due to negative attitudes toward cooperation, personal conflicts, and inadequacies of human and information resources. Institutions should try to acquire U.N. and other intergovernmental publications in their areas of interest. These are often distributed free. Information systems should also acquire indigenous sources of information and use them not only for developing their own collections but also for gifts and exchange purposes. Furthermore, in cooperation with the parent organization, libraries and information centers should promote indigenous publishing, including the use of desktop publishing and online publishing tools.

User Sensitization and Training Issues

Two critical factors in successfully implementing IT projects in developing countries are user sensitization and user training. The UNESCO document Com.74/NATIS/3 highlights the issue of awareness in NATIS objective 2, which states among other things

In many parts of the world, even though information is available in the collections of documentation, library and archives services, the potential users of these facilities are unaware of their existence and the advantages they offer, or the information remains unused because it does not meet the special needs of specific sectors of the community.

The same document further recommends the following:

In order to increase user awareness, appropriate bodies, including universities and other educational institutions should include in their programs systematic instruction in the use of the information resources available in all of the elements of NATIS. It is therefore recommended that: use of libraries should be part of instruction offered from the primary school level onwards so that seeking information becomes a normal part of daily life; the efforts of stimulation of user awareness and user education started within the educational programs should be continued in professional life, and research workers should be encouraged to seek and use the specialized literature which would help them carrying out their research and development programs.^[6]

Another significant UNESCO document, *Education and Training of Users of Scientific and Technical Information: UNISIST Guide for Teachers*, clearly underscores the significance of user training.

In every country, from the least developed to the most advanced, a certain amount of scientific and technological

information—locally produced or of the international origin—is processed and stored in some fashion for the benefit of users. Unless these users know how to find relevant information, the information “machinery” falls short of its main goal.^[80]

Indeed, many information professionals, academics, IT experts, and regional institutions have underlined the importance of user sensitization and training in various regions of the Third World. Syed Salim Agha and Akhtar, in their study on sustaining information systems in developing countries, recommended promotion and marketing of an information system to existing and potential users in order to enhance awareness and use of its products and services.^[17] Likewise, Bell asserted that information systems that are available do not always advertise themselves as well as they might, leaving the service to be discovered by those who want it. He further argued that the lack of use, or underuse of information systems, might relate to lack of user education.^[19] Keylard pointed out that the bulk of users and information professionals are inexperienced.^[38] In the same vein, Paez Urdaneta advocated that one of the objectives of the information implementation strategy in developing countries should be stimulating and increasing the demands.^[81] The need for user sensitization and education in Africa has also been widely recognized. One of the major objectives of PADIS is to organize training courses and seminars for users of the system.^[47]

In the Middle East, Alkoudasi advanced in his proposal for a structure for Arab scientific and technological information and computer networks that one of the major objectives of the envisaged IIP-ARABNET, a network linking willing S & T institutions in the Arab region, should be to enhance the national and regional capacity for information handling and use through, among other things, increasing the awareness and enhancing the capacity of potential users of information and data through the promotion of greater utilization of existing facilities (ENSTINET, KISR, RSS, SSRC, etc.), as well as orienting them toward more effective use of the available services.^[82] In Saudi Arabia, one of the recommendations of the National Science Foundation (U.S.), which conducted a feasibility study in 1977 on the development plan for a national information system for science and technology for the kingdom, recommended among other things that SANCST should train users and libraries in the use of online services.^[27] In the same vein, Saleh Ashoor and Zahir Khurshid conducted a study on user reaction to the online catalog at the University of Petroleum and Minerals Library (the present KFUPM library) in 1985, and identified a training program to maximize the use of the computer catalog as well as an updated manual as two of the major areas needing improvement. They subsequently recommended that there should be a help desk near the terminals staffed by librarians during specified hours to give users instructions on the use of the catalog.^[83]

The objectives of user sensitization and training programs in developing countries include stimulating user awareness and use of IT-based information systems; dispelling the fear of using IT or IT phobia; dispelling misconceptions about the potential as well as limitations of IT-based systems; and imparting basic and advanced information retrieval and life-learning skills. In short, the goal of user training in developing countries should be imparting information literacy skills. The target population of user sensitization and training programs should not only include students, but must also include different types of users, ranging from policy makers, academics, researchers, professionals, and technicians to workers. Referring to online searching, Marghalani identified the need to inform the academic community about the service and recommended that an effective plan to publicize online searching service to all users should be developed.^[84] Planning of user sensitization and training programs should involve all information professionals who would be directly involved in implementing the programs. Concerted efforts should be made to win the support of the organization's senior administrators. Planning and implementing awareness and training programs may be frustrating because of the lack of appreciation of the importance of information, and thus low attendance. Patience, vigilance, vigorous efforts, and flexibility are therefore vital in the planning, organization, and implementation of user sensitization and training programs. Their timing should avoid coincidence with any other major activities taking place in the organization.

In organizing a user-sensitization program, the head of the library/information center could start with enlightening the organization's management on the significance of valuable information resources and services provided by the information system. In doing so, it should be emphasized that these resources are vital for realizing the mission of the organization. This is important to win their support. The chief executive of the organization may be invited to open the event, while heads of departments may be invited to attend as well as to encourage members of their departments to attend. A combination of instructional methods and formats, including group discussions, on-the-spot demonstrations, hands-on practice, seminars, workshops, open house, videos, online tutorials, and library Web page is likely to be more effective than the lecture method. Al Hadidy, in his study on delayed online searches in Egypt, suggested that effective means of user education should include brochures, live demonstrations, and seminars in the user's departments, as well as fliers and posters. Print materials, including flip charts, simple search guides on a particular system, and handouts are useful in giving tips on effective search strategies and techniques.^[33] Users cannot entirely rely on the bulky and too-detailed documentation provided by vendors; simple guides tailored to the needs of the user community are more useful.

In order to enhance user awareness about the existence and availability of information resources and services, library information systems have been involved in compiling and distributing bibliographic listings. These listings include acquisition or accession lists, bibliographies such as topical and geographic bibliographies, pathfinders, and directory information. With the application of IT, many of these bibliographic services have been computerized. For example, POPIN-Africa, a project based in the population division of the U.N. Economic Commission for Africa in Ethiopia used to produce monthly accession lists by using MINISIS CDS/ISIS software packages. POPIN-Africa also published *POPINDEX-Africa* an indexing and abstracting journal, as well as *Country Bibliographies* and the *Directory of African Demographers* out of the POPIN-Africa referral database.

In Saudi Arabia, KACST provides an electronic current awareness bulletin to researchers in the kingdom. The International Livestock Center for Africa in Ethiopia, the Tanzania Literature Service, and the Zambia Literature Service also disseminate information to their participating centers through current awareness and document delivery services based on photocopying and distributing tables of contents as well as supplying desired articles. Information systems have also used library publications such as brief information leaflets and basic guides, as well as detailed library handbooks for user sensitization. These publications are processed by using IT such as word processing and desktop publishing, such as Ventura and Page Maker. Graphic software packages have also been employed in designing publicity posters and brochures. Recently some library and information services have started disseminating information by using library home pages as well as electronic bulletins. Communications technology, especially fax machines, E-mail, and telephones are useful delivery media for disseminating information on IT systems. Special events may also be used to disseminate information. Such events may include an open house, distribution of publications, and demonstrations of IT-based resources and services.

Libraries and information centers in developing countries may take advantage of major events in the library/organization to provide awareness/user training programs. For example, the KFUMP library in Saudi Arabia uses Library Awareness Day, an annual event at which newcomers are introduced to library resources and services while the returnees are updated on the latest developments in the library to invite researchers to conduct comprehensive searches on their special areas of interest. Apart from aggressive publicity that may include the use of posters located in key important areas, announcements in the organization or library newsletter, word of mouth, and electronic bulletins, E-mail, and other electronic communication media may be effective in user sensitization. Offering free refreshments may attract a great number of children and students, while conducting comprehensive

searches in users' fields of interest may lead to a positive response from researchers, faculty members, and other serious researchers. A quiz may also attract positive participation, especially if some prize is awarded. In addition to the activities mentioned above, other items that would be included in a user sensitization program would include demonstration of IT-based information services such as CD-ROM and online searching, access to network resources through national, regional, and international networks such as Bitnet and Internet resources, and searching of online public access catalogs. Publications on IT-based systems may be distributed. Publicity information such as leaflets, fliers, or publicity jackets may be more effective than detailed documentation.

The discussion above have pointed out that for a successful implementation of user sensitization and training programs, management, marketing, communication, teaching, and evaluation skills are desirable. These skills are particularly crucial for public services information specialists who may be involved in the planning, actual implementation, and evaluation of the programs. Unfortunately, however, many public services librarians lack marketing and teaching skills. Worse still, these proficiencies are inadequately covered in many library and information science education or continuing education programs. Information professionals should therefore pursue and participate in professional development programs pertinent to information management, communication, marketing, teaching, and learning.

While the responsibility of organizing user sensitization programs may rest with the information centers or library services, user training programs may be organized and implemented in partnership with the computer services department or any other department interested in offering user training programs pertinent to IT-based information systems. It is important to evaluate user sensitization and user training programs in order to ascertain whether the programs have achieved their objectives. This may be accomplished through analyzing statistics of attendance and observing whether those who participated in user sensitization and training programs use the automated information systems and services more frequently since their participation in user training programs. A simple suggestion form may be distributed to participants during the promotion event to solicit comments and suggestions. After offering promotional events for a couple of years, an evaluation of the overall program may be conducted. A survey instrument may be used to elicit information on the magnitude, frequency, and adequacy of user-sensitization program objectives, planning and organization, content, and methods.

As for the evaluation of user training on IT-based information services, an immediate evaluation may be carried out by using a simple questionnaire instrument to elicit information on whether the patron understood the information presented in the programs—the adequacy of the information provided and the level of confidence attained in

using IT-based systems independently as a result of their participation. The simple questionnaire may be completed and submitted right after the user-training session. A more detailed questionnaire may be administered to participants or nonparticipants after a couple of months to ascertain why nonparticipants who had been identified did not attend and how useful those who attended found the programs.

CONCLUSION

This entry has discussed some major issues pertinent to planning, implementing, and managing IT projects in developing countries. It has contended that IT projects can positively contribute to socioeconomic development, but due to numerous problems, the contribution of information and IT to development has been questionable. Hardly any significant positive impact has been observed. Worse still, IT has often led to the widening of the gap between the rich and the poor within the developing world as well as between the developing and the industrialized countries. It is therefore recommended that developing countries should carefully plan for the implementation of IT projects. While the selection of hardware and software may be primarily determined by the requirements as ascertained through needs assessment, the existing IT environment, including the availability of technical support and cultural factors, should also be given serious consideration.

Although a variety of IT projects have been effectively applied to a number of operations of library information systems such as online searching, CD-ROM searching, and access to network resources, developing countries with poor information infrastructure may like to continue exploiting CD-ROM technology. Nevertheless, CD-ROM should be supplemented by access to other electronic network resources such as the Internet and intranet resources. This entry has also underscored several factors crucial for the implementation of IT projects in developing countries. Such factors include offering aggressive user sensitization, information marketing, and end-user training.

In the future, developing countries will have to apply IT to their various development activities. The question is no longer whether IT should be applied, but how it should be effectively used to solve the many diverse and complex development problems. It is strongly recommended that a strategic plan include the development and refining of new visions and adopt a partnership; a flexible and resourceful approach is vital for implementing successful and sustainable IT projects in developing countries.

Information Technology Standards for Libraries [ELIS Classic]

Christinger Tomer

School of Information Sciences, University of Pittsburgh, Pittsburgh, Pennsylvania, U.S.A.

Abstract

Information technology standards, which have been an important part of librarianship in the United States for more than 70 years, are today more important than ever. The environment in which such standards arise grows increasingly complex, as the technical concerns of librarians and archivists intersect with the communities formulating technical standards for computing, networking, and digital publishing. In this entry, the nature of standards and basic aspects of the standardization process are described, key standards-making organizations are identified and their roles are assayed, and the various benefits of information-oriented technical standards are assessed.

INTRODUCTION

With the rise of digital libraries and the emergence of digital documents as the primary means of composition and publication, technical standards have become more important than ever for libraries and other information services. In fact, information technology standards may be viewed properly by librarians and archivists as blueprints for survival, because the interoperability of systems is now essential to the continuation of high-quality library and archival services.

Technical standards have been an important part of librarianship in the United States since 1939, when the American National Standards Committee Z39, the forerunner of the current National Information Standards Organization (NISO), was formed. Today, the environment in which technical standards bearing on libraries arise grows increasingly complex, as the rise of the Internet and the World Wide Web engage a wide array of organizations and interests in the development and use of technical standards, and the technical concerns of librarians and archivists have intersected with those communities formulating technical standards for computing, networking, and digital publishing. So, in the early twenty-first century, organizations like the Internet Engineering Task Force (IETF), International Organization for Standardization (ISO) and the World Wide Web Consortium (W3C) play prominent roles in the development of technical standards that have significant effects on digital libraries and archives, and on digital publishing.

Technical standards “are the basis for making many exciting and empowering things happen – like connecting one system to another, producing files on one system that can be transferred to another, and saving users money when a different manufacturer’s less expensive component can be connected to their system.”^[1] Or, to cite another view, “[w]ithout standards no one can use intelligent machines very effectively, equipment cannot interoperate,

and all the information people are so busy creating would stay locked in files and archives, largely inaccessible.”^[2] Perhaps even more to the point, Lynch has written:

We are beginning to recognize that standards documents are really a form of “public good,” reflecting and recording achievements of intellectual consensus among a broad community of developers, rather than representing acts of individual creative authorship. They serve as a social construct and intellectual record.^[3]

Looking ahead, it is clear that as the desire for more and more interdependence grows, technical standards will only increase in importance. It is also clear that the development of open technical standards like those developed by NISO, ISO, IETF, and W3C are critical factors in the broader advance, penetration, and benefits of information technologies.

THE NATURE OF STANDARDS

What is a standard? How are standards developed? How specifically are information technology standards developed? These are vital questions, because understanding standards and the role of standards requires an understanding of the nature of such specifications and the processes leading to their acceptance.

A number of relevant definitions are available. According to the ISO, a standard is “a document, established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context.” The ISO stipulates further that standards should be based on the consolidated results of science, technology, and experience, and aimed at the promotion of optimum community benefits.^[4]

The general view is that “a standard is the deliberate acceptance by a group of people having common interests or background of a quantifiable metric that influences their behavior and activities by permitting a common interchange.” In addition, it is held that a standard represents the belief of its authors that its specifications will be “understood, accepted, and implemented by the market,” and that standards are formulated with the expectations of substantial effect on the markets that they address.^[5]

The British Standards Institution states that:

... a standard is an agreed, repeatable way of doing something. It is a published document that contains a technical specification or other precise criteria designed to be used consistently as a rule, guideline, or definition. Standards help to make life simpler and to increase the reliability and the effectiveness of many goods and services we use. They are intended to be aspirational – a summary of good and best practice rather than general practice. Standards are created by bringing together the experience and expertise of all interested parties such as the producers, sellers, buyers, users and regulators of a particular material, product, process or service.^[6]

With specific reference to information technology standards, the ISO stipulates that the “purpose of IT standardization is to ensure that products available in the marketplace have characteristics of interoperability, portability and cultural and linguistic adaptability,” and that standards should therefore reflect the following “Common Strategic Characteristics”: repeatability; interoperability; portability; and cultural and linguistic adaptability.^[7]

TYPES OF STANDARDS

There are several types of technical standards, including conceptual and implementation standard and process and product standards. The first type of standard is the conceptual standard. Conceptual standards usually constitute the detailed articulation of a proposal to produce a new technology or induce a revolutionary change in the way in which a process is conducted. For example, the IEEE 802.3 Ethernet standard, which was conceived so that individual computer users might have access to remote facilities such as printers, is rooted in problems of effectiveness and efficiency and predicated on the idea that facilitating communications between computer users and systems resources affords a basis for maintaining high levels of both performance and service at acceptable costs. Although implementation of this conceptual standard led more or less directly to the development of the local area network and an array of technologies necessary to support specific aspects of the service envisioned in the standard, the standard itself is conceptual in nature.

The second type of standard is the implementation standard. Implementation standards are typically evolutionary as opposed to revolutionary in nature, and tend to reinforce existing industry patterns. An example of this type of standards work is efforts aimed at ensuring that a programming language, which exists in various versions, is implemented properly.

Today, the notion of the implementation standard extends to digital document formats, such as the Portable Document Format (PDF) and the OpenDocument Format (ODF). In the case of the PDF, after more than 15 years of proprietary development, Adobe Systems decided in 2007 to release the PDF specification to the Association for Information and Image Management (AIIM), with the understanding that AIIM would work with and through the ISO to establish PDF as an open standard. PDF had become a *de facto* global standard for information exchange and archival storage (and Adobe had already worked within the ISO process to deliver specialized subsets of PDF as standards for specific industries and functions), but the powers-that-be at Adobe decided that the most effective way to continue to advance this particular technology was to make the underlying specification an open standard, so that other developers had a readily available reference standard in implementing PDF writers, readers, and other applications. The standard, ISO 32000-1:2008, specifies “a digital form for representing electronic documents to enable users to exchange and view electronic documents independent of the environment in which they were created or the environment in which they are viewed or printed.” The standard also specifies that “[i]t is intended for the developer of software that creates PDF files (conforming writers), software that reads existing PDF files and interprets their contents for display and interaction (conforming readers) and PDF products that read and/or write PDF files for a variety of other purposes (conforming products).” PDF/Archive (PDF/A) and PDF/Exchange (PDF/X) are ISO standards.

The ODF is a file format for electronic office documents, such as spreadsheets, charts, presentations, and word-processing documents. The specifications were originally developed by Sun Microsystems, in conjunction with its development of an office productivity suite called Star Office, and the standard was further developed by the Open Office Extensible Markup Language (XML) technical committee of the Organization for the Advancement of Structured Information Standards (OASIS) consortium. Based on an XML format originally created and implemented by the OpenOffice productivity suite, the open source version of Star Office, the purpose of the ODF is to establish a basis for the creation and exchange of formatted documents based on open standards and without reliance on any specific application.

The standard was published as an ISO/IEC international standard, ISO/IEC 26300:2006 Open Document Format for Office Applications (OpenDocument) v1.0.

Development of the Open Document Format continues, with the expectation that version 1.2 will be approved by the ISO in 2009. Its importance was reinforced and expanded in 2007, when Microsoft announced that beginning with Microsoft Office 2007 Service Pack 2 native support for the ODF will be included.^[8] Microsoft also released the specifications for the binary document formats associated with Microsoft Office, and indicated that subsequent versions of Office would also include native support for the PDF. At this writing, there is reason to believe that as a result of Microsoft's commitment to ODF, digital documents are about to enter a new and even more productive era, since the use of the ODF as the default format for documents generated under the Microsoft Office productivity suite will enhance interoperability at the document level, presumably in great measure.

A third type of standard is the product standard. Typically, a product standard describes an existing product or service and establishes the characteristics of the product or service as a model for other products of the same type within a specific industry.^[9] Product standards, *de facto* or *de jure*, are commonly derived from products that dominate specific markets; recent examples of *de facto* product standards include the file format supported by a popular computer application like Microsoft Excel or a widely used peripheral device.

Finally, there are process standards, which are concerned with the transformation of a need into a solution, but not with the products that produce the transformation. In other words, process standards are generally device independent specifications. An example of such a standard is ISO 8879: Standard Generalized Markup Language (SGML), a meta-language providing a standard syntax for defining descriptions of classes of structured information and rules to structure information that led to the development of the Hypertext Markup Language (HTML), which is, in its various forms, an SGML document type definition (DTD). Under SGML, a set of DTDs is established, and then segments of a document (e.g., the title statement, the bibliography, or illustrations) are labeled in accord with the DTDs, thus dividing the document into named, logical elements. The advantage of using a standardized language for describing documents in structural terms is that a single source document may be processed by a wide array of applications, where those applications are capable of interpreting SGML, thus liberating the interchange of electronic documents from the realm of specific applications and proprietary document structures. Today, SGML has been superseded by the XML, which is:

... a simple, very flexible text format derived from SGML (ISO 8879). Originally designed to meet the challenges of large-scale electronic publishing, XML is also playing an increasingly important role in the exchange of a wide variety of data on the Web and elsewhere.^[10]

HOW STANDARDS ARE MADE

The process under which standards are made varies from organization to organization, but the development process employed by NISO is, in general terms, representative. New standards are proposed by NISO's Topic Committee as a "work item," when it can be demonstrated that the proposed standard is relevant to NISO's purposes, that its development is feasible, and that it warrants the requisite investment. A proposed work item includes a working group charter, a description of the proposed standard, a suggested timeline for development, and a description of related standards. In the second phase of the process, if the work item is approved, a working group is recruited and then approved by the Topic Committee. (Approval of a work item requires that 10% of the NISO membership votes in favor of the item.) In the third phase, a work plan, timeline, and budget are created and approved by the Topic Committee. The work plan is then implemented, with the plan typically divided into a data-gathering phase and the development of the draft standard. In the fifth phase, assuming support by two-thirds of the working group, the draft standard is forwarded to the Topic Committee, with the recommendation that NISO release it as a Draft Standard for Trial Use or for ballot. If two-thirds of the Topic Committee approve, the trial use period runs from 6 to 18 months. If and when a draft standard secures the approval of the Topic Committee, the Architecture Committee, the majority of the NISO Board of Directors, and the direction of NISO's managing director or a petition from 5 or more voting members of NISO, a standard ballot is issued. Once the standard goes to ballot, there is a 60-day public review period, followed by a 45-day voting period. If a majority of the "voting pool" casts ballots and two-thirds of those votes are in the affirmative, the draft standard is approved. (Comments must be addressed and resolved before the standard is officially published.) In the next phase, the standard is submitted to American National Standards Institute (ANSI) for approval, under a nine-stage process administered by ANSI. Once ANSI approval has been secured, NISO establishes a maintenance agency or a standing committee, in either instance assuming responsibility for changes, clarification, and interpretation.^[11]

THE BENEFITS OF TECHNICAL STANDARDS

Technical standards offer several important advantages. First, the process of developing technical standards affords a structured basis for exchanging relevant ideas and information. In addition, technical standards offer what has been termed a collaborative advantage, meaning that developers, particularly the developers of standards that are prospective in nature, often have a substantial amount of time in which to investigate the implications of a new

standard or a revision of an existing one. Of equal importance, open standards create a more competitive environment, and that usually provides consumers with a wider array of choices and lower prices. For organizations such as libraries and archives, standardization has been a crucial factor in making computing and networking economically feasible.

STANDARDS-MAKING BODIES

Who makes standards? The realm of standards making is a complex one, ironically lacking a high degree of standardization. Industry or interindustry groups, treaty organizations, professional organizations, government agencies, and ad hoc vendor groups each make standards.

On the international scene, the ISO is the primary standards-making body, but other organizations, such as the International Telecommunication Union (ITU) also play important, sometimes crucial, roles in the development of technical standards. The ITU has been engaged in standardization work since 1865, when the International Telegraph Union was established. The ITU became a United Nations specialized agency in 1947. It was renamed the International Telecommunications Union in 1993. An example of an ad hoc vendor group with a long-standing interest in standards making is The Open Group. Originally known as the Open Software Foundation (OSF), it was organized in 1988 for the purpose of standardizing the Unix operating system, and continues as an industry consortium to set vendor- and technology-neutral open standards for computing infrastructure. Another such group is the European Computer Manufacturers Association, which has been active in defining a framework and developing standards for Computer-Aided Software Engineering (CASE).

In the United States, the principal standards-making body is the ANSI, which charts committees and accredits other groups to formulate standards. NISO is one of the bodies that ANSI accredits for the purpose of developing standards in a specific area. Standards of the federal government, not necessarily inconsistent with the standards devised by ANSI and its allied organizations, are developed by the National Institute of Standards and Technology (NIST), with considerable influence from other federal agencies, including regulatory agencies such as the Federal Communications Commission and the nation's largest consumer of goods and services, the U.S. Department of Defense. Some unaccredited standards bodies, such as the IETF and Internet Architecture Board, are also highly influential. The IAB supports the development of documents that define standards for the Internet protocol suite. The IAB has developed these standards in order to coordinate the evolution of the Internet protocols. The majority of Internet protocol development and standardization activities takes place in the working groups of the IETF. Protocols that are to become standards in the Internet go

through a series of steps: proposed standard, draft standard, and standard. Each step in this process involves increasing amounts of scrutiny and experimental testing. At each step, the Internet engineering steering group of the IETF must make a recommendation for advancement of the protocol and the IAB must ratify it for the process to move forward. If a recommendation is not ratified, the protocol is returned to the IETF for review and further development. It is a general practice of the IAB that no proposed standard can be promoted to draft standard without at least two independent implementations and the recommendation of the Internet engineering steering group. Promotion from draft standard to standard generally requires operational experience and demonstrated interoperability of two or more implementations, as well as the recommendation of the Internet engineering steering group.

THE ANSI

The ANSI is a private, nonprofit organization that approves national standards and coordinates a system for voluntary standardization. Founded in 1918, ANSI is also the U.S. representative to the ISO and the International Electrotechnical Commission (IEC). Its membership includes more than 125,000 organizations, including corporations, government agencies, and professional, technical, trade, labor, and consumer organizations.

ANSI is the official U.S. representative to the ISO and, via the U.S. National Committee, the IEC. ANSI is also a member of the International Accreditation Forum (IAF). At the regional level, ANSI is the U.S. member of the Pacific Area Standards Congress (PASC) and the Pan American Standards Commission (COPANT). It is also a member of the Pacific Accreditation Cooperation (PAC) and Inter American Accreditation Cooperation (IAAC). ANSI's mission is:

To enhance both the global competitiveness of U.S. business and the U.S. quality of life by promoting and facilitating voluntary consensus standards and conformity assessment systems, and safeguarding their integrity.^[12]

THE NISO

The NISO is accredited by the ANSI to develop voluntary technical standards for libraries, publishers, and the information industry. Its mission is to foster "the development and maintenance of standards that facilitate the creation, persistent management, and effective interchange of information so that it can be trusted for use in research and learning."^[13] In addition, NISO serves as the expert technical advisory group to ANSI on international standards concerning information sciences, documentation, and libraries developed by the ISO/technical committee 46.

NISO is supported by a number of organizations, ranging from the American Library Association, the American Society for Information Science and Technology and the Modern Language Association to the Library of Congress, Online Computer Library Center (OCLC), the U.S. Government Printing Office, Reed Elsevier, and Recording Industry Association of America. At present, NISO has more than 70 voting members, who assist in the development of new standards and review all the standards developed by NISO.

In addition, the Library Standards Alliance, which has 27 members, has been established in order to provide libraries a role in NISO's activities. The members of the Library Standards Alliance include Boston College, the British Library, Columbia University, Harvard, the Library and Archives Canada, the NIST, Ohio State, Princeton, Stanford, the Universities of Chicago, Florida, Maryland, and Notre Dame, and the World Bank.

Throughout its history, NISO has been concerned with the formulation and implementation of standards that address the needs of libraries and archives, information services, publishing, and the book trade in a series of areas, including information transfer, forms and records, identification systems, publication formats, transliteration, preservation of materials, and library equipment and supplies. Today, NISO's mission includes identifying areas in which standards are needed; developing, writing, and maintaining voluntary technical standards; reviewing and updating current standards; and representing national interests in the development of international standards.

More than 35 NISO standards are currently in print, and a substantial number of other standards are being developed or revised at this writing. Standards produced to date include specifications for bibliographic information interchange, the construction and formatting of indexes, a Common Command Language (CML), interlibrary loan data elements, patron record data elements, and international standard numbering for both books and serials. Each NISO standard is reviewed as a matter of policy after five years in force.

In the past, NISO has been largely reactive in its dealings with the library community, and has not been engaged in the "incubation or early development of standardization efforts." In recent years, however, NISO has begun to work on standards-related activities that go beyond its traditional portfolio of Z39.xx standards and its relationship with ISO. According to strategic plans established in 2005, in the future NISO will be engaged in the development of other outputs, including "recommended practice documents; tools, plugins, or Web services definitions; white papers investigating and educating on new technologies; registries in support of identifiers and other processes; and creation of "living documents" such as wiki sites (with an editorial board)." Under the new framework, another goal is to accelerate the standards-making process by compressing both the

incubation and testing periods for draft standards, so that the process which begins with a concept and culminates in final approval of a standard typically requires less than two years. ("Final approval" in this case is a majority vote of NISO members, not the full consensus needed for approval of an ANSI Z39-track standard.)^[14] Under NISO's previous system, the initial phase of standards development in the NISO environment took two to three years. At the end of this period, a draft of the proposed standard entered into a round of comments and revisions that could take another 12–18 months, followed by a vote of the NISO membership. If the proposed standard was approved, a resolution phase followed, during which the changes necessary to achieve consensus are sought in order to finalize the standard. Finally, ANSI reviewed and approved the new standard prior to publication. It was not unusual for this process to span a period of 5–8 years. This is a formidable task, given that acceptable, useful standards must be clear and reflect consensus, neither of them being qualities that are easily achieved.^[15]

CURRENT NISO STANDARDS

Some of the key NISO standards have been in place for years. Examples include the Information Interchange Format, ANSI/NISO Z39.2, which is the basis for the MARC (Machine-Readable Catalog) record and the standard for serial numbering, ANSI/NISO Z39.9. Of the newer standards, several are likely to be of critical importance, including ANSI/NISO Z39.88, the OpenURL Framework for Context-Sensitive Services, which defines an architecture for an open framework for information services in networked environments; ANSI/NISO Z39.29, which establishes rules, guidelines, and examples for bibliographic references; ANSI/NISO Z39.85, the Dublin Core Metadata Element Set, defining metadata elements for resource description in cross-disciplinary information environments; and ANSI/NISO Z39.93, the Standardized Usage Statistics Harvesting Initiative (SUSHI) Protocol, which defines an automated request and response model for the harvesting of electronic resource usage data within a Web services framework.

THE ISO

On the international scene, about 100 countries have national standards bodies that bring together experts from industry and universities to develop standards. In addition to ANSI, prominent standards-making bodies include Deutsches Institut fuer Normung (Germany), the British Standards Institution, Association française de normalisation (France), Ente Nazionale Italiano di Unificazione (Italy), Nederlands Normalisatie-instituut (Netherlands), Standards Australia, the Standards

Association of New Zealand, Norges Standardiseringsforbund (Norway), Dansk Standard (Denmark), and the ITU. The is the organization that coordinates the activities of national standardization bodies at the international level. Together with the IEC, ISO concentrates its efforts on “harmonizing” national standards all over the world. The results of these activities are published as ISO standards.

ISO has 157 national members, out of the 195 total countries in the world. The ISO’s Central Secretariat, which coordinates the system, is located at Geneva, Switzerland.

There are three categories of membership in ISO. Member bodies are national bodies that are considered to be the most representative standards body in each country. Member bodies are the only members of ISO that have voting rights. Correspondent members are countries that do not have their own standards organization. Subscriber members are countries with small economies. Correspondent and subscriber members are informed about ISO’s work, but they do not participate in standards-making process.

As a matter of policy, ISO standards are developed on the basis of consensus, taking into account the interests and views of manufacturers, vendors and users, consumer groups, testing laboratories, governments, engineering professions, and research organizations. ISO standards are intended to be global solutions that address and satisfy the requirements of industries and consumers on a worldwide basis. Finally, ISO standards are voluntary, and their promulgation is based on the view that international standardization is and should be a market-driven process.

ESTABLISHING ISO STANDARDS

There are three principal phases in the ISO standards development process. In the first phase, the need for a standard is articulated, usually within an industrial sector, and then communicated to a national member body. The national member body then proposes the new work item to ISO. If the need for an international standard is recognized, the technical scope of the proposed standard is defined, usually by a working group of experts from countries interested in the subject matter of the proposed standard.

Once agreement has been reached by the working group on the technical aspects to be covered under the proposed standard, the second phase of the process begins, during which the detailed specifications of the proposed standard are reviewed and revised by representatives of the member bodies. It is during this phase of the process that the consensus building necessary for the eventual approval of the proposed standard occurs. In the final phase of the process, the draft standard is taken to ballot, with formal approval requiring affirmation by two-thirds of the ISO members that have participated actively in the standards-development process and 75% of all members voting on the draft standard. Following formal approval,

the text of the standard is published as an ISO International Standard. (Most standards require periodic revision, owing to factors such as technological evolution, new methods and materials, and new quality and safety requirements. Consequently, ISO mandates that all standards should be reviewed at least once every five years.)

At this writing, ISO has published more than 16,000 standards, including the metric system of units, international stationery sizes, rules for technical drawings, electrical connectors, security regulations, computer protocols, file formats, bicycle components, ID cards, programming languages, international standard book numbers (ISBN), barcode symbology, and RFID. Within the ISO, the ISO/IEC Joint Technical Committee 1, which is maintained in collaboration with the IEC, deals with information technology. The ISO/IEC Joint Technical Committee 1 was formed in 1987 by merging ISO/TC 97 (Information Technology) and IEC/TC 83, with IEC//SC 47B joining later, thereby establishing a single approach to information technology standardization by and for the two parent organizations. Its mandate is to develop, maintain, promote, and facilitate information technology standards in the following areas:

- Design and Development of IT Systems and Tools
- Performance and Quality of IT Products and Systems
- Security of IT Systems and Information
- Portability of Application Programs
- Interoperability of IT Products and Systems
- Unified Tools and Environments
- Harmonized IT Vocabulary, and
- User-Friendly and Ergonomically Designed User Interfaces.

Membership in the ISO/IEC Joint Technical Committee 1 is open to any national body within either of the parent organizations. Other organizations may participate as liaison members. Membership in the ISO/IEC Joint Technical Committee 1 expanded substantially in 2007, immediately prior to the initial vote on Office Open XML as DIS (Draft International Standard) 29500.

ISO STANDARDS RELEVANT TO LIBRARY AND INFORMATION SERVICES

Although the ISO is engaged in the development of standards in many different areas, most of the ISO standards that are applicable to libraries and related information services are standards addressing specific issues in computing and networking. There is, for example, the Linux Standard Base (LSB), a joint project by several Linux distributions under the organizational structure of the Linux Foundation to standardize the software system structure used with the Linux operating system. The LSB, which is based on the POSIX (Portable Operating System Interface) specification, the Single UNIX Specification,

and several other open standards, was submitted for approval as ISO/IEC 23360 in 2008. Another recent example is the PDF. Developed by Adobe Systems for document exchange and in widespread use since the mid-1990s, PDF was officially published as an open standard in 2008, as ISO 32000-1:2008. PDF encapsulates a complete description of a fixed-layout two-dimensional document (and, with Acrobat 3D, embedded 3D documents), including the text, fonts, images, and vector graphics which comprise the document. Last but not least, there is ISO 8879: 1986, which describes the SGML, a format for storing documents together with their logical structure and layout information in a standardized scheme and the basis for the HTML, and which is effectively the precursor of contemporary documents standards, such as ISO/IEC 29500-1-4:2008, which defines a set of XML vocabularies and other conventions for representing word-processing documents, spreadsheets, and presentations, based on the Microsoft Office 2008 applications, and ISO/IEC 26300:2006 Open Document Format for Office Applications (OpenDocument) v1.0, which defines an XML schema for office applications and its semantics in more expansive terms.

An ISO standard more directly relevant to the interests of libraries (and illustrative of the conditions that influence the evolution of technical standards) is ISO 23950, also known as ANSI/NISO standard Z39.50. Designed as a protocol for searching and retrieving information, usually from bibliographic records, Z39.50 specifies procedures and formats for a client to search a database provided by a server, retrieve database records, and perform related information retrieval functions.

Z39.50's design predates the World Wide Web, relying on now largely outmoded connection oriented, program-to-program communication. As a result, substantive work aimed at updating and revising the protocol has been under way since 2000, leading thus far to the development of two new protocols, SRU (Search and Retrieve via URLs) and SRW (Search/Retrieve Web Service), and a synthetic query language, the Contextual Query Language (CQL), intended to support their implementation. (The CQL is a formal language for representing queries to information retrieval systems. The language represents an effort to combine the qualities of more powerful, more expressive query languages such as SQL, PQF, and XQuery with simpler, more intuitive languages, such as the CCL and Google's search syntax.) The suite encompassing SRU, SRW, and CQL was originally called "Z39.50 Next Generation," and then later it was known as "Z39.50 International Next Generation" (ZING). Today, neither designation is used. Development of SRW/SRU/CQL began in 2000. An experimental version, 1.0, was released in 2002, and the first official version, 1.1, in 2004. A minor revision, 1.2, was released in 2007.^[16]

SRU is based on Representational State Transfer (REST), a collection of network architecture principles

that specify how resources are defined and addressed, and enables queries to be expressed in URL query strings. SRW uses SOAP, the Simple Object Access Protocol, a specification for exchanging structured information within the framework of Web services, as the basis for the expression of queries. SRU and SRW address the same information retrieval problems that Z39.50 confronted, each of them relying on XML as their message and results format.^[17]

The OASIS Search Web Services Technical Committee is developing a unifying model for Web-based search and retrieval services that incorporates SRU/CQL and Amazon's OpenSearch, with the expectation that other protocols will be integrated into this model at a later date.^[18] One of the goals of this effort is to lower the barrier to entry for developers through a reliance on existing Web services technologies.

Other, library-oriented ISO standards include: ISO 15511:2003 Information and documentation—International Standard Identifier for Libraries and Related Organizations (ISIL); ISO 9230:2007 Information and documentation—Determination of price indexes for print and electronic media purchased by libraries; ISO/TR 21449:2004 Content Delivery and Rights Management: Functional requirements for identifiers and descriptors for use in the music, film, video, sound recording, and publishing industries; and ISO 11620:2008 Library performance indicators.

W3C

The W3C was established in 1994, as an industry consortium dedicated to building consensus around Web technologies through the creation of relevant standards and guidelines. Tim Berners-Lee, who invented the World Wide Web in 1989 while working at the European Organization for Nuclear Research (CERN), was one of the founders and has served as the W3C Director since its inception.

Since 1994, W3C has published more than 110 such standards, called W3C Recommendations. The goal of the W3C is to maintain and promote "Web interoperability," which means that for the World Wide Web to reach its full potential, the basic technologies must be device and platform independent, vendor neutral, and fully compatible with one another. The W3C works to avoid the fragmentation of the Web by developing and publishing open, nonproprietary standards for Web languages and protocols. According to Berners-Lee:

W3C is where the future of the Web is made. Our Members work together to design and standardize Web technologies that build on its universality, giving the power to communicate, exchange information, and to write effective, dynamic applications—for anyone, anywhere, anytime, using any device.

In 2008, the W3C has more than 400 member organizations from more than 40 countries. As part of its dedication to the internationalization of the Web, the W3C instituted a number of changes to its fee structure in 2005 to encourage participation from organizations in developing countries.

W3C's operations are supported by a combination of dues, research grants, and other sources of public and private funding. The MIT Computer Science and Artificial Intelligence Laboratory (CSAIL), the European Research Consortium for Informatics and Mathematics (ERCIM), and Keio University in Japan, provide administration jointly. In addition, the W3C maintains regional offices around the world, to promote W3C technologies in local languages, broaden its geographical base, and encourage international participation.

A main focus of the activities of the W3C is to make the World Wide Web and its services "available to all people, whatever their hardware, software, network infrastructure, native language, culture, geographical location, or physical or mental ability." Work in areas such as Web accessibility, internationalization, device independence, and the so-called mobile Web is emphasized. (The goal of W3C's Mobile Web Initiative (MWI), which was launched in 2005, is to make Web access from any kind of device as simple, easy, and convenient as Web access from a desktop.) In addition, the W3C is committed to fostering "technologies that enable a more collaborative environment, a Web where accountability, security, confidence, and confidentiality are all possible, and where people participate according to their individual privacy requirements and preferences."

W3C ACTIVITIES

W3C activities are organized into groups: Working Groups (for technical developments), Interest Groups (for more general work), and Coordination Groups (for communication among related groups). The groups, made up of participants from Member organizations, the Team, and Invited Experts, produce technical reports, including Web standards, open source software, and services. These groups also ensure coordination with other standards bodies and technical communities. At this writing, there are currently 23 activities incorporating and managing 77 groups.^[19]

MAJOR W3C ACHIEVEMENTS

W3C's most important achievements fall into four broad categories. First, there are the specifications that relate to digital documents, including Cascading Style Sheets, HTML, the Document Object Model (DOM), XML, and Compound Document Formats. Second, there are the metadata standards, RDF and OWL. These technologies, which have been designed to support the Semantic Web by providing structured descriptions and addressing

ontological issues, respectively, provide a standardized framework for asset management, enterprise integration, and the sharing and reuse of data on the Web.

Third, there are the access-oriented initiatives, including the Web Accessibility Initiative (WAI), the MWI, the Internationalization Activity, and the development of standards supporting multiple, simultaneous modes of interaction. Finally, there are the coordinating efforts aimed at providing the infrastructure necessary to realize the goals embedded in Berners-Lee's notion of the Semantic Web. An example of this sort of activity is the work done by the Technical Architecture Group and expressed in *Architecture of the World Wide Web, Volume One*.^[20]

THE IMPORTANCE OF TECHNICAL STANDARDS IN LIBRARIANSHIP

Standards, which are important to any organization that proposes to connect technologies of different types and made by different manufacturers, are especially important to libraries, because neither libraries nor librarians are able to exercise great influence over the creation or design of the technologies on which so much of their future depends. With the emergence of digital libraries, the reliance on standards has expanded, including not only hardware and software, but also digital documents, metadata, network-based services, and schemes for accounting and management of related information activities. Perhaps more to the point, a generation of documentation has been built on the basis of various digital document formats, including the Microsoft Office formats and the PDF, as well as open HTML and XML, and as we look to the future, there is reason to believe that the work of the W3C in the area of compound document formats will become increasingly important, as various agencies work to make digital documents richer, more informative, and more useful.

In each instance, the key issue is and will continue to be interoperability, which is defined under ISO/IEC 2382 Information Technology Vocabulary as "the capability to communicate, execute programs, or transfer data among various functional units in a manner that requires the user to have little or no knowledge of the unique characteristics of those units." From a systematic perspective, interoperability assumes that the objects of interaction, including metadata, can be exchanged across systems, that as a result an aggregated content layer may be constructed on the basis of resources drawn from a distributed system of digital libraries, and that technological standards enabling different kinds of interoperability, including more traditional approaches geared toward librarian metadata interoperability such as Z39.50, harvesting methods based on OAI-PMH (Open Archives Initiative-Protocol for Metadata Harvesting), and/or Web service-based approaches, constitute a critical dimension in achieving and maintaining this capability.

THE FUTURE

As always, the future is uncertain. However, if recent history is a sign, it is likely that more and more standards bearing on information technology in general and libraries in particular will be formulated and promulgated. The reasons will be many and varied, but in the end the proliferation of standards (and standards-making bodies) will constitute a collective, rational response to the increasing complexity of the information environment, as well as an expression of the need for continuity, both diachronically and synchronically.

It seems reasonable to imagine, too, that the standards-making process itself will be a matter of increasing interest, particularly as the economic benefits of standards in information technology and allied areas are more clearly understood.^[21,22] Such trends will intensify the longstanding debate over the speed and complexity of the standards-making process, especially when it is coupled with the growing sense that the responsibility for maintaining, information technology and library standards has become too diffuse and perhaps too chaotic.

Information Theory

Paul B. Kantor

School of Communication and Information, Rutgers University, New Brunswick, New Jersey, U.S.A.

Abstract

Information theory “measures quantity of information” and is that branch of applied mathematics that deals with the efficient transmission of messages in an encoded language. It is fundamental to modern methods of telecommunication, image compression, and security. Its relation to library information science is less direct. More relevant to the LIS conception of “quantity of information” are economic concepts related to the expected value of a decision, and the influence of imperfect information on that expected value.

THE FUNDAMENTALS OF INFORMATION THEORY

Information theory traces its origin to technical work done by Claude Shannon of Bell Laboratories, in the late 1940s.^[1] Communication engineers wanted to determine the largest amount of information that could be transmitted when noise on the “channel” (which was, at the time, a cable carrying electrical waves) made the signal at the receiving end different from what was originally sent.

Shannon introduced measures of the amount of information, of the capacity of a channel and of the noisiness of the channel, and by combining them was able to prove important mathematical results relating the “rate of transmission of information” to the “capacity of the channel” and the amount of “noise.”

Unpredictability, Random Variables, and Information

The capacity required to transmit a message, even through a channel which has no noise in it at all, depends on the unpredictability of the characters in the message.

The discussion of unpredictable messages requires the mathematical concept of a “random variable.” An entity is represented mathematically as a random variable when it may take any one of a specified set of values, and, over the long term, the relative frequencies of those alternatives remain steady. The frequencies will then converge to numbers which represent the probabilities of the several alternatives. The choice among them is (subject to these probabilities) not controlled by any known forces, and thus is regarded as random. As an example, the result of a coin toss can be represented by a random variable. In the field of economics, the concept is extended to events that do not repeat many times, and one speaks of “the probability of a nuclear reactor accident” or similar rare events.

A random variable is completely characterized by specifying the allowed set of values, and the probability that it takes on each of its possible values. We can represent this by displaying the alternatives and the probabilities together in an array, as shown in Eq. 1:

$$FairCoin = \begin{bmatrix} .5 & .5 \\ \text{head} & \text{tail} \end{bmatrix}; BiasedCoin = \begin{bmatrix} .8 & .2 \\ \text{head} & \text{tail} \end{bmatrix} \quad (1)$$

The expression in brackets corresponding to the random variable *FairCoin* means that the event “head” occurs with probability 0.5 or 50%. So does the complementary event “tail.” The second expression represents a random variable, *BiasedCoin*, which assumes the value “head” 80% of the time and the value “tail” only 20% of the time.

Equally Probable Alternatives

Shannon showed that the relation between the amount of information in a message and the number of different possible values that the message might have is a logarithmic one. This can be understood in an intuitive way by the following simple argument. Suppose that we have to send a message about which of three alternatives, let us say {A, B, or C} is true. And we also have to send a message about which of some other four alternatives, let us call them {1, 2, 3, 4} is true. For example, suppose we want to specify that we will meet for one of three meals, {breakfast, lunch, or dinner}={A,B,C}, and will do so on one of four days: {Monday, Tuesday, Wednesday, or Thursday}={1,2,3,4}.

Whatever the amount of information required to specify one out of three alternatives is, and whatever the amount of information required to specify one out of four alternatives is, taken together the amount of information that they provide is enough to specify one out of 12 alternatives, as there are $12 = 4 \times 3$ possible combinations. The only continuous

function which has the required property: that it be additive when its arguments are multiplied, is the logarithm.

Therefore, when there are N equally possible alternatives, the “amount of information” required to specify one of them should be related directly to the logarithm of N . Logarithms may be computed to any base. It is customary in communication to compute the logarithm to the base 2. The resulting number is measured in “bits” (binary digits). For example, $\log_2(8) = 3$ bits.

Varying Probabilities and the Entropy Measure

The situation is more complicated when the alternatives are not equally probable, which leads to the very important concept of entropy. The entropy, or amount of disorder, is a concept previously known for physical systems, which Shannon used very effectively in the discussion of messages.

Shannon showed that this unpredictability could be characterized by a numerical function which is called the entropy of the message. The higher the entropy of the message, the longer the string (or the larger the “alphabet”) required to transmit it accurately, and the more “information” it carries.

The entropy is a mathematical function which represents the amount of uncertainty presented by a random variable, in terms of the set of probabilities of the outcomes. If the values of a particular random variable whose name is X are represented by the numbers $1, 2, 3, \dots, n$, and their corresponding probabilities are represented as $p_1, p_2, p_3, \dots, p_n$ then the entire random variable can be represented, in the notation of Eq. 1 as

$$X = \begin{bmatrix} p_1 & p_2 & p_3 & \dots & p_n \\ 1 & 2 & 3 & \dots & n \end{bmatrix}. \quad (2)$$

The entropy of this random variable, $H(X)$ is defined by the equation:

$$H(X) = - \sum_{i=1}^n p_i \log_2(p_i) \quad (3)$$

If a particular alternative cannot occur, the corresponding term in the sum is 0. If, for example, there are 16 alternatives, and each of them is equally likely, then each of the probabilities $p_i = 1/16 = 2^{-4}$. Thus $-\log_2(p_i) = 4$. The whole sum consists of 16 identical terms, each equal to $-p_i \log_2(p_i) = 1/16 \times 4$, and thus the sum (the entropy) is equal to 4. This is precisely the logarithm to the base 2, of the number of equally probable alternatives. It can be shown mathematically that this is the largest value that the entropy can have, when there are 16 possible alternatives. If, for example, one of them were enormously more probable than the others, one of the terms in the sum

would have the value $-(1-\delta)\log_2(1-\delta)$ (where δ is a very small positive number). This number becomes proportional to δ when δ is small, and vanishes as δ goes to zero. At the same time, all of the other terms in the sum vanish because they have vanishingly small probability. So when one of the possible outcomes is nearly certain, the entropy is nearly 0. The entropy formula can be shown to satisfy all other requirements of a “reasonable” measure of the quantity of information, and it is unique, up to a constant factor. We have, in effect, selected that constant factor by choosing to use logarithms to the base 2, rather than to the base 10, or the base of natural logarithms, e .

The Entropy of a String of Characters

The entropy can be defined for any situation in which there is a series of events or symbols, which are determined to some degree, by those that precede them. As a concrete example, we might consider an alphabet containing only the three letters a, b, c . From these 3 letters we can form 9 ($= 3 \times 3$) two letter “words”: $aa, ab, ac, ba, bb, bc, ca, cb, cc$. Similarly we can form 27 ($= 3 \times 3 \times 3$) three letter “words”: $aaa, aab, aac, aba, abb, abc, acb, acc, baa, bab, bac, bba, bbb, bbc, bca, bcb, bcc, caa, cab, cac, cba, cbb, cbc, cca, ccb, ccc$. Thus it would appear that when we specify which one of those three-letter sequences occurs, we have specified 1 out of 27 possibilities. If they are equally likely, then the entropy, or amount of information, will be given (to three decimal places) by $\log_2(27) = 4.755$. On the other hand, if we know in advance that the three letters will form a complete word in the English language, there is only one possibility, and the amount of information conveyed when we see the string cab is, in the sense of information theory, 0. Finally, if we know only that the string will be the whole or a part of an English word, then there are several more possibilities, including acc, bab, bac , and perhaps others. In this case the amount of information conveyed when we see the string is greater than 0, but less than 4.755. Thus, in the sense of Information Theory, the amount of information conveyed by a message is related to the number of possible messages that might have been received.

This concept has been applied, on a character-by-character basis to compute the entropy of the English alphabet, given that the 26 letters (and the space character) are being used to form (possibly meaningless) English expressions. The result is usually given as about 1.5 bits per letter.^[2] (Luenberger^[2] is an excellent introduction for a reader comfortable with elementary algebra, elementary calculus, and elementary probability.)

The Mutual Information in a Pair of Random Variables

When there are two random variables that have some relation to each other, the strength of that relation can be

measured in many ways. Shannon approached this problem by considering the amount of information in the pair of random variables (observed together) and comparing that to the amount of information in observation of each of the variables separately. Specifically, using the definition of entropy as given above, we can calculate the entropy of each variable separately, and of the two variables together. This is somewhat complicated, and example calculations are shown in Table 1.

Combining the information in Table 1, we calculate the Mutual Information $M(X,Y)$ of the two random variables X and Y according to the formula of Eq. 4.

$$\begin{aligned} M(X,Y) &= H(X) + H(Y) - H(X,Y) \\ M(\text{meals}, \text{days}) &= 1.44 + 1.79 - 2.91 \\ M(\text{meals}, \text{days}) &= 0.32 \text{ bits} \end{aligned} \quad (4)$$

This is a relatively weak relationship. A stronger one is shown in Table 2. The mutual information in that case is, in fact, precisely equal to the information about which meal I designate. The joint information is precisely equal to the information about the day on which I meet. This is because, when the day is specified, with these probabilities, the meal is completely determined, and knowing the meal in addition to the day, adds no information. Note that although the day determines the meal, and the meal does not determine the day, the mutual information is symmetric.

This is because, if we want to convey information about the meals, by reporting only the days, we can cleverly choose the “days” to remove the ambiguity. Note that we have moved here from describing a “real world” to a situation where we are trying to exploit the probabilistic relation between meals and days to convey information about one of the two, when it is expressed in terms of the other. So the connection to Shannon theory is to imagine that, for example, we want to tell someone about the day, but the nature of our “communication channel” is such that when we choose a day, the recipient is told the name of a meal, according to the probabilities specified.

The situation in Information Theory has some additional freedom for the sender of the message. I could choose to use the “days” as a kind of code. For example, I might represent the letter P by the code string {Monday, Thursday, Tuesday}. The situation becomes quite complex, and this entry provides only a brief introduction.

The reader may verify, by detailed calculations, that if there is a one-to-one correspondence between the two variables, the mutual information is equal to the information in either of them separately.

Communication and Mutual Information

Being employed by the telephone company, Shannon was concerned with the real-world situation in which the

Table 1 The information in joint variables and in the variables separately.

Case I					
Probabilities					
	Breakfast	Lunch	Dinner	Which day (1)	Logarithms ⁽¹⁴⁾
Monday	10%	30%	10%	50%	−1.00
Tuesday	0%	15%	0%	15%	−2.74
Wednesday	5%	0%	10%	15%	−2.74
Thursday	5%	10%	5%	20%	−2.32
Which meal (2)	20%	55%	25%	100%	$H(\text{days}) = 1.79$
Logarithms (5)	−2.32	−0.86	−2.00	$1.44 = H(\text{meals})$	

The numbers in the cells represent the probability that my lunch meeting falls on each specified meal and day. Let us say that I meet only once per week. Thus there is a 30% chance that the meeting, in a particular week is Monday lunch. There is only a 5% chance that the meeting of the week, for me, is Thursday dinner. Of course these numbers add up to 100% as shown in the lower corner of the table. We can also compute the probability that I meet on each particular day (1), or that I meet for each particular meal (2). These sets of numbers themselves each sum to 100% separately. Using an additional column (4) to record the logarithms (to the base 2) of the “by day probabilities” I have enough information to compute the entropy of the “by day” information. It is 1.79 bits. [Each logarithm is multiplied by the probability to its left, and the products are summed]. This is the amount of information conveyed, or the amount of uncertainty resolved, by determining on which of the 4 days I meet for a meal. Note that although there are four possible days, this amount of information is less than $2 = \log_2(4)$ because the days are not equally likely. Similarly, I could work with the totals in the columns, multiplying them each by their logarithms, and summing the results to yield the entropy of the “which meal” information, which is 1.44 bits. This is less than $1.58 = \log_2(3)$, again because the meals are not equally likely.

Logarithms	Breakfast	Lunch	Dinner	
Monday	−3.32	−1.74	−3.32	
Tuesday	0.00	−2.74	0.00	
Wednesday	−4.32	0.00	−3.32	
Thursday	−4.32	−3.32	−4.32	$H(\text{meals}, \text{days}) = 2.91$
Mutual Information = 1.44 + 1.79 − 2.91 = 0.32				

Finally, we can calculate the information in the array of information about days and meals. To see how this works, we display the logarithms of the probabilities in this small table. Multiplying each logarithm by its corresponding probability, and summing the numbers yields the entropy of the joint distribution. This is the number, 2.91, referenced in the text.

Table 2 A stronger information relation.

Probabilities					
	Breakfast	Lunch	Dinner	Which day	Logarithms
Monday	10%	0%	0%	10%	−3.32
Tuesday	0%	35%	0%	35%	−1.51
Wednesday	0%	0%	45%	45%	−1.15
Thursday	0%	10%	0%	10%	−3.32
Which meal:	10%	45%	45%	100%	H(days) = 1.71
Logarithms	−3.32	−1.15	−1.15	1.37 = H(meals)	

The numbers above could represent the fact that if I send a message such as “Monday” it will **definitely** arrive as “Breakfast.”

Logarithms	Breakfast	Lunch	Dinner	
Monday	−3.32	0.00	0.00	
Tuesday	0.00	−1.51	0.00	
Wednesday	0.00	0.00	−1.15	
Thursday	0.00	−3.32	0.00	H(meals, days) = 1.71
Mutual Information = 1.71 + 1.37 − 1.71 = 1.37				

signals initially sent over a telephone cable could be distorted or affected by “noise,” with the result that the signal received at the other end of the cable is not precisely the one that was transmitted. To address this problem, he defined two concepts: *the rate of information transfer*, and the *capacity of the channel* (or cable) itself.

As suggested above, suppose that we wish to send information as to which specific day we have in mind. But we are constrained to do this not by naming the *day*, but by, instead “transmitting” specific information about *which meal* we ate, and asking the recipient to decode that information, and decide which *day* we mean. To be specific, in Table 3, we show a relationship in which only the day “Tuesday” corresponds to more than one meal. If we avoid “Tuesday” then the message that he receives will be unambiguous. For example, if we want to indicate “Monday” he will receive the message “Breakfast.” And he will know that this corresponds only to Monday. But we have to avoid Tuesday because in that case the message could be either “Breakfast” or “Dinner” and this will introduce ambiguity into the decoding.

We can choose how often we send the message corresponding to each particular day. As we have mentioned above, balancing them equally will transmit the largest amount of information, provided that we never choose Tuesday. This is because Tuesday sends an ambiguous message: the meal might be breakfast or dinner. If we choose among the remaining days in an unbalanced way, we decrease the amount of information that we can transmit.

Using these ideas, Shannon was able to establish his Second Theorem of communication. This expresses the amount of information that can be communicated. The highest possible amount is called the capacity of the channel. In its most fundamental form this is given in terms of maximizing the mutual information, as described above.

$$\text{Capacity} \left\{ \begin{array}{l} \text{When a message} \\ \text{about } X \text{ is received it} \\ \text{terms of signals } Y \end{array} \right\} = \underset{\text{all distributions of } X}{\text{maximum}} M(X, Y) \quad (5)$$

Here, the maximum means that we choose how often each message X is sent, in order to get the best possible communication. Strictly speaking, as was articulated by subsequent research, this is the limiting rate when the source of the message is “ergodic,” which means, roughly, unpredictable, or having maximum entropy when viewed as a sequence of characters in whatever alphabet is being used.^[3] There are many implications of this formula. Some variants deal with the specific case where the values assumed by the variables X and Y are both binary. Other variations take account of the entropy of the message to be sent.

In all real cases the difficult technical problem is to find a scheme for encoding which comes as close as possible to the theoretical limiting rate. This involves considerable ingenuity, and there are many open problems.

In addition to this mathematical and engineering focus of Information Theory, the book by Shannon and Weaver,^[1] included a speculative essay by Weaver on the possible general implications of these results for behavioral sciences in general, and opened other worlds for exploration.

INFORMATION THEORY TODAY

Sixty years later the field of Information Theory, whose central professional society is the IEEE Society for Information Theory, is flourishing. The problem of finding the actual encoding which will come close to the Shannon theoretical limit is a difficult one leading into complex fields of mathematics.

The corresponding methods for the compression of information are part of our everyday lives, especially for users of the Internet. They range from the use of zipped compression to reduce the size of files, to the complex compressions involved in the jpeg and mpeg conventions for static and moving images.

Table 3 Another relation between the intended message (the day) and the code used to represent it (the meal). The entry is the probability that a given message is received, given what message is sent

Intended message	Message received			$P(X)$	$-\text{Log}(P)$
	Breakfast	Lunch	Dinner		
Monday	100.0%	0.0%	0.0%	33%	1.58
Tuesday	50.0%	50.0%	0.0%	0%	0.00
Wednesday	0.0%	0.0%	100.0%	33%	1.58
Thursday	0.0%	100.0%	0.0%	33%	1.58
$P(Y)$	33.3%	33.3%	33.3%	33%	
$-\text{Log}(P)$	1.58	1.58	1.58	100.0%	

Here we represent the fact that if I send the message “Monday” the recipient is certain (100%) to get the message “Breakfast.” Alternatively, we might say that I am “encoding” “Monday” by sending the message “Breakfast.” However (perhaps due to noise in the transmission process, when I encode “Tuesday” the recipient gets the message “Breakfast” 50% of the time and “Lunch” 50% of the time. This introduces ambiguity. We can think of it as noise in the transmission process. If I insist on sometimes sending the message “Tuesday” then I cannot achieve the full channel capacity.

Probabilities $P(X,Y)$

	33.33%	0.00%	0.00%		
	0.00%	0.00%	0.00%		
	0.00%	0.00%	33.33%		
	0.00%	33.33%	0.00%		
				100.00%	
$E(Y)$	1.5850				
$E(X)$	1.5850				
		Note: $1.05850 = \log_2 3$			
Logarithms of $P(X, Y)$					
	1.58	0.00	0.00		
	0.00	0.00	0.00		
	0.00	0.00	1.58		
	0.00	1.58	0.00		
$E(X, Y)$	1.5850				
$M=E(X)+E(Y)$					
$-E(X, Y)$	1.5850				

Progress on the social science side has also been energetic, but has not proceeded in the directions anticipated in Weaver’s essay.

Human Communication

Scholars in the field called Communication (e.g., the National Communication Association, NCA, of the United States) concern themselves primarily with the social contexts and functional roles of communication. In their analysis it is never important to attempt to quantify the “amount of information” that is being communicated. Thus the approaches pioneered by Shannon have only rhetorical impact in that field.

Library and Information Science

In the field of Library and Information Science, it has seemed that one might want to know something about the relation between the “amount of information” and something else, which Brookes^[4] has called the “increase in knowledge.” Brookes proposed that the phenomenon of importance to information science is that the transmission of information *to a suitable recipient* results in an increase in the amount of

knowledge “held by” that recipient. The idea, while often referenced, does not seem to have led to any serious attempt to provide a measurement of either the “amount of information” or the “increase in quantity of knowledge.”

Economics

The third social scientific discipline which concerns itself with information is Economics. In Economics there has been an effective effort to quantify the notion of the value of information. It is clear that information has economic value, since, for example, information about tomorrow’s stock prices could be immediately converted into economic gain. Economic theory has further developed, drawing upon the von Neumann and Morgenstern theory of games^[5] and economic behavior, a concrete way of measuring the economic value of information which is uncertain or noisy, in precisely the way that the channels described by Shannon are.

Utility theory

However, the detailed theory works out rather differently. The essential concept is “utility,” an abstract measure of

worth which behaves in a very specific way with respect to uncertain situations. In particular, the utility measure of an uncertain event, or “lottery,” L , such as

$$L = \left[\begin{array}{cc} p & 1-p \\ A & B \end{array} \right], \quad (6)$$

which is represented by the expression $u(L)$, is required to satisfy the equation

$$u(L) = pu(A) + (1-p)u(B) \quad (7)$$

This equation will continue to be satisfied if the utility is transformed to any new scale of the form: $u_{\text{new}}(X) = b^2u(X) + c$, for any real numbers b and c . This means that the utility is measured on an interval scale, whose zero point and unit of measure may be set at any convenient values.

Utility theory applies to decision makers, who are assumed to be able to (perhaps implicitly) assign a utility value to every situation that they might need to consider. This assignment is called the decision-maker’s “utility function”: $u_{\text{decision-maker}}(X)$. Utility theory is related to observable behavior by the requirement that a “rational” decision maker who values specific situations X, Y , according to a specific utility function for which $u_{\text{decision-maker}}(X) > u_{\text{decision-maker}}(Y)$ will definitely prefer to be in situation X , rather than in situation Y . It can be shown that a decision maker who does not follow Eq. 7 when making decisions about lottery can be systematically caused to make decisions which, over the long run, will reduce his cumulated utility. This is the specific sense in which Eq. 7 is interpreted as representing rationality.

A decision may depend on the current estimates of probability

The application of utility theory for measuring the value of information is made clear by a simple example of a two-fold decision involving an uncertain outcome. Suppose, for example, a decision maker must decide whether or not to carry an umbrella, and assigns the following utilities to the four possible alternative situations:

- A = carry an umbrella and have it rain.
- B = carry an umbrella and not have it rain.
- C = not carry an umbrella and have it rain.
- D = not carry an umbrella and not have it rain.

Specific values for these parameters are shown in Table 4a.

This information can be used to create a graph as shown in Fig. 1a, where the abscissa is the probability that it will in fact rain, and the ordinate is the utility value to the decision maker. The two straight lines on the graph represent the expected utility of the two possible actions, both of which depend on the probability that it will rain. The value of the choice or action “carry an umbrella” is

Table 4a Specific choices for the utility function of a decision maker.

State	Action	
	Not carry	Carry
No rain	0	2
Rain	2	-1

low when the probability of rain is low, but increases as the probability of rain increases. The value of “not carrying the umbrella” is high for low probabilities of rain, and decreases as the probability of rain increases. An important feature of this situation is the value of the probability at which the two lines cross, which we call the “critical probability” for this utility function. According to the principles of utility theory, the decision maker will not carry an umbrella if the probability is less than this value, will carry an umbrella if it is greater than this value, and is indifferent when the probability of rain is equal to the critical value.

Imperfect information can improve the expected utility of a situation

The preceding discussion describes the situation, without any information, or the “prior situation.” Suppose now that the decision maker is offered an imperfect or “noisy” prediction of whether it will rain. We can calculate the expected value of “being in the situation of having this information” and compare it to the expected value in the present situation. The difference can, of course, be interpreted as the “value of the information.” The mathematics is somewhat complicated. To begin with, an imperfect prediction can be imperfect in two distinct ways: failing to predict rain, on rainy days, and predicting rain on days when there is no rain. These two numbers are independent of each other, and both are needed to complete the calculation. We denote the first probability by “ t ” for true alarm or warning, and the second by “ f ” for “false warning.” The information can be summarized as in Table 4b or Table 5.

The second complexity comes in interpreting a prediction which is known to be inaccurate in this way. This is accomplished using Bayes’ rule,^[6] which relates the probability of rain, given the imperfect information, p_1 , to the prior probability of rain p_0 . That equation is given in terms of odds ratios as

$$\begin{aligned} \frac{p_1}{1-p_1} &= \frac{t}{1-t} \frac{p_0}{1-p_0} \quad \text{if the prediction is “rain”} \\ \frac{p_1}{1-p_1} &= \frac{f}{1-f} \frac{p_0}{1-p_0} \quad \text{if the prediction is not “rain”} \end{aligned} \quad (8)$$

For a reasonable weather predictor, the first of the numbers p_1 , found by solving these equations, will be higher

Fig. 1 (a) As the probability of rain increases, the utility of not carrying an umbrella decreases. Correspondingly, the utility of carrying an umbrella increases. In this case they cross at 40%, the critical probability. The decision maker, according to his estimate of the probability, chooses the action corresponding to the higher line. His expected utility, as a function of the probability, never falls below the crossing value. (b) With an imperfect predictor of rain, the decision maker can still improve his expectation, in some situations, but not all. The “bridge” in this diagram shows the higher utility that can be achieved if 1) his estimate is close enough to the critical point; and 2) he makes use of the prediction. The expected utility increase, due to using the prediction is the rational basis for assigning “value” to the prediction. Note that the same prediction will have higher value for a decision maker whose original estimate of the probability is closer to the critical value. This is quite different from entropy measures, which increase as the probability nears 50%.

than the second; that is, it is more likely to rain if the prediction is “rain” than if it is “not rain.” Let us refer to them as p_H and p_L , respectively (H for high; L for low). Having this prediction, the decision maker will then refer to his personal utility diagram. If the result of the prediction leaves the probability below p_C , he will not carry an umbrella. If the result falls above the critical probability, he will carry an umbrella. But the results of these calculations depend on the prior probability estimate: p_0 . If the prior estimate is very low, both P_H and P_L fall below p_C , and he will not carry an umbrella. If the prior estimate is very high, both P_H and P_L fall above p_C , and he will carry an umbrella, with or without the prediction. In those two situations, the information has no value to him, since he will do precisely what he would have done without the information. The value of the information is, therefore, 0.

However, for a certain range of the prior probability, spanning the critical value, the information will cause him to change his behavior. Therefore it has some potential value. The calculation of this value depends on the

principle of expected utility. In particular, it depends on the chance that the prediction is “rain.” This, as we see from Eq. 8, depends on prior estimate of the probability. One might ask: “doesn’t it really depend on the chance of rain?”. But there is no way the decision maker can know the truth. He is restricted to choosing between his prior belief and the available imperfect prediction. In other words, if he buys the information, he will face a lottery where the outcomes are “predictions he receives” and he must compute the probability that each will occur.

$$\left[\begin{array}{cc} \text{probability prediction is “rain”} & \text{probability prediction is not “rain”} \\ p_H & p_L \end{array} \right] \quad (9)$$

Note that for any given belief about p , the probability of rain, the computed probability of the prediction “rain” contains two terms, corresponding to the true and false predictions. Thus:

$$\begin{aligned} p_H &= tp + f(1 - p) \\ p_L &= (1 - t)p + (1 - f)(1 - p) \end{aligned} \quad (10)$$

Table 4b Specific performance characteristics of an imperfect predictor of rain.

Performance of the predictor	Truth	
	Rain	Not
Rain	0.9	0.3
Not	0.1	0.7

Table 5 The accuracy of a prediction of rain.

Prediction	Truth	
	Truth = rain	Truth = not rain
Rain	t	f
Not rain	$1 - t$	$1 - f$

Note that the sum of these two probabilities is 1, since the predictor must make *some* prediction.

The decision maker can then apply Eq. 7, carrying through the calculations. The result is a third line segment on the graph of expected utility, as shown in Fig. 1b. It forms a “bridge” above the intersection at the critical probability. The left-hand end of the bridge falls at the lowest prior probability for which the information has nonzero value. The right-hand end of the bridge falls at the highest prior probability for which the information has nonzero value. The expected value of the information, in units of the decision-maker’s utility, is the vertical distance between the bridge and the higher of the original two lines, at the specific value of the prior probability. For further details see, for example, Hirshleifer and Riley.^[7]

Thus we see that the expected value of the information depends not only on the unreliability of the prediction (that is, on the numbers t and f) but also on the decision maker’s own prior estimate of the probability of rain. While the first two parameters represent the kind of information about uncertainty that is addressed by Information Theory, the dependence on the prior probability is quite a different matter. This complexity has prevented the development of any accepted theory that relates the expected value of information, in a decision situation, to computations of the type introduced by Shannon. Some efforts to develop an alternative to the Shannon formulation are discussed by Renyi.^[8]

Behavior Beyond Expected Utility Theory

The field called Behavioral Economics addresses the many ways in which observed human behavior does not easily fit with the specific assumptions of utility theory. For example, if there is a set of possible situations, then the decision maker should be able to select one of them, or be indifferent among two or more. But experiments showed^[9] that if the set is not small (i.e., contains more than six or seven alternatives) decision makers will report pair preferences that are not transitive, which is inconsistent with the notion that preferences correspond to inequalities relating real numbers (the values of the utility function). Leaders in behavioral economics include Daniel Kahnemann^[10] and Amos Tversky.^[11]

The question of whether the notion of utility can be broadened beyond the formulation given here, to accommodate apparently irrational human preferences, remains open. An interesting discussion, from the perspective of a philosopher, has been given by Nozick.^[12] He proposes that, in addition to economic utility, dealt with as above, human decision makers base their actions on a separate property of actions, which he calls “symbolic utility.” There is no conversion between these two utilities, and so, the model does not make specific predictions about behavior.

The study of behavior in the context of the theory of evolution suggests that actions that do not provide calculable utility gain for the individual decision maker may be the result of complex evolved behavior which has net utility for the genome of which the individual is a particular instance. (“A person is the gene’s way of making a new gene.”) This is an area of intense study, but no irrefutable demonstrations of the principle have been shown, for human behavior. It has been reported that the *Toxoplasma gondii* protozoan affects the brains of infected rodents in such a way as to decrease their innate fear of cats, enabling the parasite to progress to its next reproductive stage, which takes place in cats.^[13] One possible example in humans is infection with the thirst for education, which causes young adults to sacrifice productive and child-bearing years to the pursuit of academic degrees, and thus perpetuate the academy.

SURPRISE AND IDENTIFICATION

There are some relatively new streams of research which show promise of beginning to capture the element of information that is most salient from the perspective of library information science: the degree to which the message received causes a change in what the recipient already knows or believes.

Surprise

The computer scientist Pierre Baldi^[14] has proposed that messages can be judged on a scale which measures their “surprise” value. The analysis is based in part on measures related to the entropy. Specifically, he uses a measure called the Kullback-Leibler^[15] measure, which assesses the difference between one probability distribution and another, when both describe the same basic set of outcomes. The analysis adds the notion of Bayesian updating, as discussed in economics section above. When information is received the recipient is presumed to alter his prior beliefs about the probability distribution, to yield a new distribution. The “distance” (the Kullback-Leibler measure is not a proper metric in the geometric sense, but could be converted to one if needed) of the new distribution from the old is a measure of the “surprise” that the information represents to the recipient.

Identification

The information scientist Rudolf Ahlswede^[16] has developed a line of research that is somewhat dual to classical Shannon theory. He considers the problem of a recipient who knows in advance the list of messages that might be sent and wishes to determine, with at least a specified probability of being correct, which of the messages has, in fact, been sent to him. The capacity of channels,

measured against this criterion, becomes different (and, roughly speaking, higher). At a very superficial level, it appears that this line of thinking might eventually develop into a convergence between the Library/Information Science view of the problem (in which the possible messages are constrained by language, social roles, customs of expression, etc.), and the more rigorous theory which has produced so many striking improvements in the storage and transmission of the messages themselves.

CONCLUSION

In addition to its own practical contributions to our lives, it appears that the most concrete translation of the original hope that information theory might contribute to the social sciences is in the field of economics. However, in that setting, rigorous analysis shows that the value of information is not in any simple way functionally determined by the quantity of information as it was defined by Shannon. Very recent developments may eventuate in a convergence of the problems, but the path to solution is not yet clear.

There are excellent sources on the Web for information about these topics, from many perspectives, and this rich field is very much open for exciting future developments.

Information Use for Decision Making

Abstract

How should we use information to make good decisions? Historically, the view has been that normatively superior decision making is the product of complex optimization processes that rationally consider and integrate all available information. Such optimization processes are well beyond the capabilities of mere mortals and in many cases are computationally intractable by any means. Fortunately, optimization processes are not always necessary: Less can be more. Simple decision processes—i.e., heuristics—used in the right environments enable fast, frugal, and adaptive decision making that can be as good as, or better than, even the most complex optimization processes. In what follows, we introduce research on ecological rationality and the science of adaptive heuristics. Our review includes 1) a brief history of the study of decision making; 2) a discussion of simple yet computationally precise heuristics, and how, when, and why they lead to superior performance; and 3) examples of how simple heuristics are starting to be used in the information sciences, such as in database literature prioritization or in the development of more user-friendly technologies. Although it may seem conventionally paradoxical, intelligent and adaptive information use often requires that information be ignored.

INFORMATION USE FOR DECISION MAKING

In the modern world, one of the leading causes of death is heart disease. As such it is easy to imagine that many people will search for information on its causes, symptoms, and treatments. But how will they search? One candidate is a keyword search in a search engine such as Google, which as of April 2008 returned about 35,500,000 “heart disease” results in less than 2/10 of a second. This is not only a lot of information, it is too much information. Given the exponential rates of information growth in science and technology this number will likely continue to grow.^[1] Can people with limited knowledge, time, and computational capacities effectively search through vast amounts of information and make good decisions under conditions of high uncertainty? Can a scientific understanding of the cognitive processes involved in human information search and decision making help us improve information technology? In short, we believe the answer to both questions is *yes*.

To begin to illustrate our perspective, consider a recent study conducted by Michael Lee and his colleagues.^[2] Lee et al. compared the performance of a leading research database (i.e., PsycINFO) with the performance of two very different systems, each based on a model of human decision making. The first model was a “rational model” that attempted to combine all information in an optimal (or near-optimal) way. This model was inspired by what has traditionally been regarded as a normative theory of

decision making. Relevance was determined using a Bayesian learning algorithm allowing additive weighting and integration of *all* available information from cues such as authors, journals, keywords (title and abstract), language of the publication, and others. When some cue was associated (or unassociated) with a relevant article the probability that another article with that cue would be relevant (or irrelevant) was updated. Eventually, search was prioritized by selecting articles with “optimal” cue configurations as those of the highest relevance.

The second decision model developed by Lee et al.^[2] for the literature prioritization task used a rather different, perhaps even paradoxical process. In sharp contrast to a rational model, the one-reason decision-making model *ignored* a considerable amount of the available information in order to prioritize choices. This model, inspired by research on simple, adaptive heuristics^[3] used cues for inferring and assigning relevance, as did the rational model. However, in this case cues were first ordered by validity from most strongly associated and relevant to least relevant. Subsequently, a literature search prioritized results by selecting articles based solely on the most relevant cue that discriminated between options (for a more detailed discussion of validity, discrimination, cue ordering, and one-reason decision-making, see *take-the-best* later in this entry). Rather than attempting to integrate and use all possible sources of information, the one-reason decision-making model made choices based on a simple heuristic process (i.e., a rule of thumb), namely it

prioritized results based only on the single most important cue that discriminated.

To assess prioritization performance, Lee et al.^[2] compared both decision-making models (rational, one-reason) with the performance of PsycINFO. As expected, results indicated that all models returned relevant articles at above chance levels. More interestingly, and to some more surprisingly, the one-reason decision-making model consistently outperformed the rational model, which in turn outperformed PsycINFO. These results add to a growing body of evidence suggesting that more complex decision making processes do not necessarily provide superior decision-making performance. Instead, superior decision making can result from simple heuristic processes when used in the right environments.

So how is it possible that a simple heuristic was able to perform so well even when compared to a sophisticated optimization process? Part of the answer is that in our fundamentally uncertain world, simplicity often leads to robustness and efficiency. Heuristics improve performance by ignoring potentially misleading information. Heuristics also confer other benefits as this type of choice process tends to be fast and efficient, relying on radically limited information search and decision rules. As well, in human, animal, and machine cognition, simple decision processes can be fine-tuned and can exploit the fit between our environmental task constraints and our available capacities, such as a human's limited attentional capacity and our adaptive ability to forget.^[4-6] In these ways and others, simple heuristics tend to produce and enable effective, adaptive judgment and decision making in many situations.^[3,7]

In this entry we will review a research program focused on adaptive behavior and cognition—or how simple heuristics, in the right environments, can make us smarter. Our entry will begin with a discussion of the history of decision-making theory and will then turn to issues of adaptive cognition, ecological rationality, and computational models of heuristics. Next, we will provide some examples of a few widely used heuristics. Finally, we close with a discussion of implications for the design of information-rich environments.

Perspectives on Rationality: A Brief History

The emergence of the modern debate on human rationality, or how people make decisions and what qualifies as a good decision, can be traced in large part to the Ages of Reason and Enlightenment (i.e., seventeenth and eighteenth centuries, respectively). During these times logic and careful, justifiable reasoning became highly prized by philosophers, empiricists, and political actors alike. As an example, consider the astronomer and physicist Pierre-Simon Laplace. Laplace's legacy includes seminal contributions to probability theory; however, more important for our purposes, he also provided a description of a fictional

omniscient being that captured the Zeitgeist of the times. This being, known as Laplace's superintelligence, was envisioned as one who would know all the details of past and present and with this knowledge could readily make good choices and predict the future with perfect certainty.^[8]

For many people, Laplace's vision of a decision maker who is omniscient and computationally unbounded may seem like an elaborate fantasy. Yet this fantasy or some version of it is fundamental to much of the research and theory in the modern decision sciences. Some readers will find this surprising, or ironically unreasonable, but models of "rational man" and *homo economicus* are among the most central and influential models used in decision science. According to neoclassical economic theory people behave as if they were *unboundedly rational* and make optimal (but not necessarily perfect) choices as if they had solved a complicated decision calculus.^[9,10] These decisions can be described by optimization processes that reflect people's maximization of their own subjective expected utilities (i.e., personal values) via multiattribute integration calculations. Such theories are at the core of dozens of models of decision making, including modern theories of motivation, attitudes, and moral judgments.^[3,7] However, even if this approach has provided interesting and useful theory, these models often conflict with empirical evidence. Psychological science has clearly demonstrated that this is not how real people with limited resources (i.e., time, attention, memory) use information to make decisions.^[7,10-13] Perhaps even more interestingly, these complicated and time-consuming processes are not even necessarily required for good, adaptive decision making.^[3,7]

In the mid-twentieth century, Herbert Simon^[14-16] introduced his notion of bounded rationality. Simon argued that, among other things, people have only limited time, knowledge, and cognitive resources, and thus human decision makers cannot carry out the types of optimization computations that were (and still are) often assumed to underlie rational decision making. In part in reaction to Simon's notion of bounded rationality, a more modern version of a rational decision maker was developed by some decision researchers. The new theory, characterized by *optimization under constraints*, was once again concerned with a complex optimization calculus that could be used to make rational choices, but in these cases the optimization processes were also subject to any one of a number of constraints.^[17] To illustrate, in some models information search was necessary (i.e., no more omniscience) and so search processes were described and thus carried a cost. However, as a simplifying assumption the information search processes were often described by yet another optimization calculus wherein search was terminated according to the optimal cost-benefit ratio. As the number of constraints increases so too do the computational complexities of the search optimization functions that must be solved, even in simple

decisions. In this way, optimization under constraints can be even *more* computationally demanding than what is required of the unboundedly rational agents. In efforts toward greater psychological plausibility, the optimization under constraints models created in some cases an even more psychologically unrealistic, and computationally unbounded, superintelligent decision maker.^[17]

To be fair, although optimization models are not accurate process models of how real people make decisions, they do in some cases predict people's decisions or tell us about what outcomes or decisions should be favored.^[18–20] For these reasons, optimization models can be valuable tools. Nevertheless, optimization models are *as-if* models of human decision making: Many decision makers behave as if they use optimization processes even though they rely on other processes.^[21–23] Unfortunately, most research focusing on as-if models is essentially uninterested in and ill-equipped to understand the psychological dynamics involved in decision making. Hence, the as-if approach to modeling decision making leaves unanswered at least two crucial questions. First, how do people actually use information to make decisions? Second, given our known cognitive constraints (i.e., our bounded rationality), how is it that real decision processes can approximate and in some cases outperform optimization processes? To answer these questions, we turn to two different but related research programs that study human decision making and heuristics.

In the 1970s, Daniel Kahneman and Amos Tversky developed the *heuristics and biases* research program in cognitive psychology.^[11,24,25] This program was aimed at understanding how people actually make decisions. Toward this end researchers worked to reveal cognitive processes (i.e., heuristics) by focusing on judgment errors and “biases.” However, in order to identify errors one must have normative assumptions (i.e., what is the appropriate standard for an accurate or good judgment), an issue that is not without controversy.^[26,27] In the case of the heuristics and bias approach, it was assumed that human cognition should be compared to a very specific set of rational, normative standards such as the outcomes of optimization processes and logic. Specifically, the heuristics and biases program searches for errors that are evidenced when people's judgments deviate from “an established fact... [or] an accepted rule of arithmetic, logic, or statistics” (p. 493).^[28] Indeed, it has demonstrated rather unequivocally that people do not reason in accord with content-blind logical laws or optimization processes, and that people often use heuristic processes for judgments and decisions.^[10,29] The research and findings on heuristics and biases have played key roles in shaping psychological and behavioral decision making research, contributing to the development of new research fields such as behavioral law and economics.^[24,30]

In spite of its many successes, the heuristics and biases program has its limitations. One of our most serious concerns is that the program has emphasized ways in which

heuristics are associated with errors, which has led some to an interpretation that heuristic use is a problem that needs to be corrected. In this light heuristics are seen as inferior choice processes designed to be used by computationally disadvantaged individuals. In contrast, other research demonstrates that heuristics (e.g., satisficing) are often powerful tools.^[16,31,32] As illustrated by the literature prioritization example in the introduction, in real-world environments these simple processes can enable adaptive decision making, matching or outperforming even the most sophisticated and time-consuming optimization processes.

Ecological Rationality: Computational Models of Heuristics

Consider for a moment a Darwinian inspired perspective on decision making. On this view, the goals and needs of organisms, such as finding food, securing mates, or protecting offspring, may or may not benefit from cognition that is logically coherent. For these organisms, fitness is best served when cognition can be tuned to ecological constraints. An organism's success will rely on the extent to which its cognition and behavior can benefit from and exploit features of its internal and external environment, regardless of how well these processes actually adhere to logical norms. An organism's ability to survive and reproduce depends on the fit between: 1) its evolved and developed capacities, 2) its cognitive processes, 3) and the structure of its natural environment. The analysis of the fit between capacities, processes, and environment is known as the study of ecological rationality.

Understanding the relationship between the mind and its environment serves as a starting point for the study of adaptive behavior and cognition.^[32] This adaptive framework has deep roots in psychology. For example, Herbert Simon has argued that “Human rational behavior is shaped by a scissors whose two blades are the structure of task environments and the computational capabilities of the actor” (p. 7).^[16] If one wants to understand how people make judgments and decisions, and why and when these processes work, one cannot examine only processes (as most psychologists do) or only environments (as most economists and sociologists do). Studying how one scissor blade cuts, or fails to cut, does not tell us how, why, or when the scissors will actually work.

In concert with the study of ecological rationality, a second key concept for the research program on adaptive behavior and cognition is the *adaptive toolbox*. This adaptive toolbox is conceived of as a collection of precisely defined cognitive heuristics and other adaptive processes that can be used both consciously and unconsciously (e.g., intuitively) to solve problems in the real world. Organisms use a number of specific tools that are well-suited to certain task environments, not entirely unlike specific wrenches and screwdrivers that are designed for specific chores.

In this way, there is no general all-purpose heuristic (or optimization calculus) that can provide the best solution for every judgment or decision. In contrast, heuristic application is more narrow and constrained, although many heuristics can be used more or less effectively across a range of situations (e.g., a screwdriver can also be used to open a can of paint). Perhaps most critically, by defining heuristics as formal computational models, one can then identify (e.g., via simulations) exactly when, how, and why certain heuristics will succeed or fail. Theoretically, this collection of adaptive heuristics provides a precisely defined, psychologically plausible alternative to as-if optimization models of human decision making.

So how is it that these simple heuristic processes can match and outperform complex optimization processes? The answer has at least two key parts. The first part has to do with computational tractability. Regardless of the extraordinary increases in computing power that we have enjoyed in recent years, for most decisions there simply is no optimization strategy that can be computed.^[3] Optimization, except in radically simplified environments, is largely computationally intractable. Even simple problems turn out to be so complex as to be impenetrable to optimization techniques. This is true of problems that are well-defined such as in games like Chess or Go, as well as for the many ill-defined problems we face in the modern world such as choosing an outfit, a dinner, a career, or a spouse. In all of these cases, heuristic processes are not only valuable but they are absolutely essential.

The second reason heuristics can perform well is that they are robust and reduce the chance of fitting noise in our environment (i.e., overfitting). Because we live in a fundamentally uncertain world, information in our environment (i.e., environmental signals) consists, of both reliable and unreliable content (i.e., noise), or in other words, information that is diagnostic and information that could lead us astray. Particularly in situations that involve high uncertainty, the trick for intelligent decision making is to *ignore* information, such as seemingly informative but ultimately irrelevant information (e.g., past performance of stocks for predicting changes in valuation). If we performed an optimization calculation for every decision that included every regularity from every previous situation, our ability to accurately predict outcomes in new environments would be crippled as it would be based on many kinds of random, non-diagnostic noise. In contrast, because heuristics are simple and exploit cognitive capacities such as our adaptive capacity for forgetting^[4] we can reduce the risk that we will overfit non-diagnostic environmental signals. Moreover, because adaptive heuristics rely on a limited search of the available information there is a good chance that they will avoid most sources of the random noise while still benefiting from a focus on the most reliable sources of information.^[33]

In addition to the performance benefits noted above adaptive heuristics confer at least one more set of

ecologically important advantages: Heuristics can provide *fast and frugal* decision making. Because heuristics can exploit our capacities (both evolved and developed), such as our remarkable capacity for highly accurate recognition memory, the time and energy needed for these decision processes are minimized. Heuristics provide essential competitive advantages (e.g., minimizing time, search, effort invested) whether one is making decisions in the wild or in the boardroom. This frugality may benefit us physiologically as our brain, which is roughly 2% of our overall mass, commonly requires between 15% and 25% of our daily energy and oxygen budget. Even simple acts of deliberative, effortful processing can significantly influence and deplete our energy stores.^[34] In these ways and others simple heuristics tend to enable adaptive decisions in ecological environments.

Heuristic Building Blocks

Advances in the science of adaptive behavior and cognition rely in large part on identifying and modeling exact heuristic processes. These processes are described by dividing heuristics into different building blocks (i.e., subprocesses), often including: 1) *search processes*, 2) *stopping rules*, and 3) *decision rules*, which are composed of either unique processes or nested combinations of other more basic heuristics. Consider the *take-the-best* heuristic.^[34] Take-the-best belongs to a family of one reason decision-making heuristics and has proven itself to be a common and effective decision tool. Take-the-best can be used when one is faced with a choice between two different options. In these cases, take-the-best orders and considers different cues (reasons) for making its decision by selecting the best option with the first cue that discriminates between the options. In simpler language, consider a preference situation in which one is trying to decide which of two colleges to attend. One way you could make a decision would be to focus on only a single factor, the one that seems most important. For some people that might be prestige, and thus when considering both Harvard and say San Francisco State University (SFSU), one would likely pick Harvard. However, if the most important consideration was which school was affordable, you might then select the public school (SFSU) where tuition is far less. In either case, the process is roughly the same and requires only a very minimum amount of search and reasoning. First identify and order the most important cues that you will use to decide and then make your choice based on the first discriminating cue (i.e., the first cue in which one option is clearly better than the other). Indeed, in investigations of real world choices such as the one described above (but also including multiple-cue inference tasks where there are known correct answers such as inferring which of two cities is larger) we see that people often make decisions with simple processes like take-the-best.^[36,37]

More formally, take-the-best is made of three precisely defined building blocks including:

1. *Search rule*: Search through the cues in order of their validity (correlation with criteria). Look up the cue values of the cue with the highest validity first.
2. *Stopping rule*: If one object has a positive cue value and the other does not (or is unknown), then stop search and proceed to Step 3. Otherwise, exclude the cue and return to Step 1. If no more cues are found, guess.
3. *Decision rule*: Predict that the object with the positive cue value has the higher value on the criterion.

Again, each of these rules precisely defines behavior, leads to a testable prediction, and therefore can be computationally modeled or evaluated empirically. Given this precision, researchers have also used mathematical analysis and simulations to tell us about the ecological rationality of heuristics, describing for example the environments wherein take-the-best will perform better and worse.^[38] To illustrate, one can analytically prove that take-the-best is associated with superior decision making in environments that have a *non-compensatory* cue structure. Any time the sum of the cue weights does not add up to the sum of the best (remaining) cue, take-the-best will perform very well. We might imagine a task of trying to model which libraries have experienced a budget growth of at least 10%. In this example we will assume that the ecological validities (i.e., the relative frequency with which a binary cue correctly predicts the criterion) of the cues are one, one-half, one-fourth, and one-eighth, where lending rates of the library are the single most important factor (i.e., more lending is most strongly associated with strong growth), the current size of the library is one-half as important, and location is half again as important. In this case, the structure is non-compensatory because the sum of the cue weights can never add up to (or compensate for) the difference between the first cue (lending rates) and all other cues (Fig. 1).^[39] Even if one finds that another library is larger and is in the perfect location, etc., these factors could not compensate if that library had low lending rates. Findings such as these can tell us both when a simple heuristic will fail and when it will work better than or at least as well as more complex decision processes. These findings also allow for insights into what decision (or inference) should be made as well as what information should actually be used and ignored in the decision-making process.

Two Memory-Based Heuristics

Many heuristics benefit by taking advantage of evolved and developed capacities. In humans, some capacities are more fundamental than others, in the sense that they

Fig. 1 A noncompensatory environment. In this environment one can see that the first (binary) cue will always make predictions that are always as accurate as any linear combination of all cues.

develop earlier and persist longer. Recognition memory is one such capacity. In many ways our recognition memory is much more sensitive and reliable than the vast majority of other mnemonic processes, something that becomes increasingly apparent as we age. To better appreciate this capacity we invite you to try an exercise: Do your best to recall the names of the seven dwarves from the story *Snow White and the Seven Dwarves*. Although many of us will have trouble recalling these characters' names nearly everyone, or at least most Americans, will immediately recognize them (Can you recognize the seven real dwarves in this list of nine: "Bashful," "Doc," "Sloppy," "Dopey," "Grumpy," "Pudgy," "Happy," "Sleepy," and "Sneezy"). As noted, recognition not only reflects a fundamental aspect of memory, it also provides a powerful cue for adaptive decision making.

Considerable research now demonstrates that when facing a choice people often rely on their recognition, or lack thereof, to help inform their inferences. This heuristic process has been formalized in the *recognition heuristic*, which is modeled as follows: "if one of two objects is recognized and the other is not, then infer that the recognized object has the higher value with respect to the criterion."^[40] The interesting theoretical finding is that sometimes *less is more*, such that ignorance will actually improve our decision making in a variety of environments. Imagine for instance that your task is to select which of two stocks to invest in. One company might be named Coca Cola Company and the other Ameritech. One way to decide between the two companies is simply to invest in the company that is recognized and familiar. If you do this, and thus decide according to the recognition

heuristic, you'd likely select Coca Cola. Although it is a simple strategy that relies largely on one's ignorance, research shows that it can match or outperform "expert" stock portfolios, in certain common environments^[41,42] (for boundary conditions see also Andersson).^[43]

By way of analysis and computational modelling it is possible to understand the conditions in which recognition will be likely to provide good (and not so good) inferences. Research indicates that recognition will lead to good decisions whenever it is correlated with a decision criterion. Consider the task of trying to decide which of two cities is larger (in population), selecting between Detroit and Houghton (MI), for example. In this case, recognition may be diagnostic as cities that have more people are also more likely to be mentioned in the media and have more major sports teams, companies, airports, events, and so on. Bigger cities are therefore more likely to be recognized and not recognizing a city becomes a valuable basis for inference. Of course, recognition does not guarantee that one city is larger than another (e.g., Hollywood, CA, vs. Fresno, CA). However, when there is a strong correlation between recognition and the decision criteria, recognition will tend to provide accurate inferences.

The *fluency heuristic*^[44,45] is a second fundamental memory-based inference process (for a recent review see Kelley).^[46] Considerable converging evidence reveals that fluency, which is roughly defined as our subjective experience of the ease of information processing (cf. availability), often dramatically influences our confidence, judgment, and decision making.^[24,25,47–49] If we again consider the real-world task of selecting stocks we find that people tend to judge that unrecognized companies with names that are easier to read (pronounce) are more likely to be profitable. This is true in laboratory studies and can also be seen in actual stock trading during initial public offerings.^[50,51] Indeed, there is a long tradition of studying fluency and availability. Here we focus on more recent research done within the adaptive framework. Specifically, we have developed the *ACT-R fluency heuristic* that formalized: "If one of two objects is more fluently processed, then infer that this object has the higher value with respect to the criterion" (p. 612).^[4] In this case, fluency is precisely defined as the speed with which declarative memory chunks can be retrieved in the computational cognitive architecture ACT-R. As with the recognition heuristic and take-the-best, the ACT-R fluency heuristic relies on a simple but powerful one reason decision-making process. The critical difference is not whether or not one recognizes some bit of information but how quickly and easily one recognizes it. The more easily one option is recognized the more likely it is to influence our decision, a process that is fundamental to a variety of adaptive inferences. Understanding these processes provides insight into the adaptive nature of our cognitive architecture. More generally, understanding the processes used by one of the most complex and efficient

adaptive devices known—i.e., the human mind—can help enable the design of better innovative engineering and information technology solutions.^[52]

Heuristics, Usability, and Environmental Design

The work of Lee et al.^[2] on search prioritization serves as an excellent example of the potential for using adaptive heuristics to improve information technology. However, this is only one side of the usability issue. Opportunities also exist to study user decision making to further understand the heuristic processes commonly relied upon in database and library type environments. Currently there is a small but growing body of work using process-oriented or otherwise ecologically grounded approaches that may be valuable for future research efforts.^[53,54] For example, some research focuses on variations in human search strategies in database environments^[55] such as differences in the processes of children and adults (Bilal and Kirby, 2002).^[61] In these studies, key results indicate that specific information search strategies can be identified that tend to systematically vary with age. Similarly, there is a somewhat more developed tradition of studying human search behavior in general consumer choices that has begun to explore Internet or database-type environments.^[57–59] These studies have also been successful in identifying search strategies, with some going a step further and identifying stopping rules and the environmental constraints that mediate heuristic selection.^[60] For instance, Browne et al. have started to identify the relationships between environmental factors and search processes, suggesting that there often exists a positive relationship between task complexity, search times, and stopping rules. Similarly, other recent work has used our understanding of human decision-making heuristics to improve human–computer interface design. By eliminating non-diagnostic or highly redundant (correlated) product-attribute information researchers limit the redundant search processes of users, which allows consumers to better cope with information overload effects including the so-called *too much choice effect*.^[62]

There are also a number of other connections between specific heuristics and library and information search behaviors that have yet to be explored. As noted, both recognition and fluency tend to influence everyday choices. In a library environment it is easy to imagine that these heuristics would influence decisions such as which book(s) to order or read (e.g., an author is recognized, an author is more quickly recognized); what search queries to use (e.g., do you recognize any results from these keywords); and when to stop searching (e.g., when further search yields little in the way of relevant recognizable information; stop search when information is no longer easily recognized or fluent). However, these simple connections and the review provided here can only serve as an introduction. There are many other heuristics and aspects of information use and search processes that may prove to

be very influential in the design of user-friendly technology (for a more complete overview see Gigerenzer).^[7,32]

CONCLUSION

There has been considerable focus on the fact that people often use heuristics to make decisions. Fortunately, in the right environment these simple heuristic processes make us smart by simplifying and speeding decisions, and by helping us ignore irrelevant information. In our complex and uncertain world simple heuristics sometimes represent the very best decision making processes available. Whether designing better information technology, better decision support systems, or better decision environments one lesson is clear: Superior decision making does not necessarily require more complex processes. Less can be much more. In these ways and others, the future holds great opportunities and promise for engineering simplicity.

Informetrics

Judit Bar-Ilan

Department of Information Science, Bar-Ilan University, Ramat Gan, Israel

Abstract

Informetrics is a subfield of information science and it encompasses bibliometrics, scientometrics, cybermetrics, and webometrics. This encyclopedia entry provides an overview of informetrics and its subfields. In general, informetrics deals with quantitative aspects of information: its production, dissemination, evaluation, and use. Bibliometrics and scientometrics study scientific literature: papers, journals, patents, and citations; while in webometric studies the sources studied are Web pages and Web sites, and citations are replaced by hypertext links. The entry introduces major topics in informetrics: citation analysis and citation related studies, the journal impact factor, the recently defined h-index, citation databases, co-citation analysis, open access publications and its implications, informetric laws, techniques for mapping and visualization of informetric phenomena, the emerging subfields of webometrics, cybermetrics and link analysis, and research evaluation.

INTRODUCTION

In the literature, several definitions have been suggested for *informetrics* and the related fields of bibliometrics, scientometrics, cybermetrics, and webometrics. In this entry, we adopt the definitions suggested by Björneborn and Ingwersen,^[1] where all the above-mentioned metrics are viewed as subfields of *informetrics*. This entry is organized as follows: first, we clarify the terminology and provide a general introduction and then we discuss the major topics of interest in the field (citation studies, theory, visualization, cybermetrics/webometrics, and research evaluation).

TERMINOLOGY AND DEFINITIONS

Informetrics was defined by Tague-Sutcliffe^[2] as “the study of the quantitative aspects of information in any form, not just records or bibliographies, and in any social group, not just scientists.” Brookes^[3] characterized *informetrics* as “a generic term that embraces both biblio- and scientometrics.” To understand Brookes’ definition, we need to define *bibliometrics* and *scientometrics*. Here we use Tague-Sutcliffe’s definitions again, she defined *bibliometrics* as “the study of the quantitative aspects of the production, dissemination, and use of recorded information” and *scientometrics* as “the study of the quantitative aspects of science as a discipline or economic activity.”

The above definitions were published at the time the World Wide Web was just “born.”^[4] Although the Internet had existed for a long time already,^[5] at the time the above definitions were published there were no quantitative studies of Internet-based and Web-based information to the best of our knowledge. Later the definition of *informetrics*

was extended as a result of the Internet and the Web becoming major information sources, and currently *informetrics* is accepted to encompass *cybermetrics* and *webometrics* as well. *Cybermetrics* is defined in Ingwersen^[1] and Björneborn^[6] as “[t]he study of the quantitative aspects of the construction and use of information resources, structures and technologies on the whole Internet drawing on bibliometric and informetric approaches,” and *webometrics* as “[t]he study of the quantitative aspects of the construction and use of information resources, structures and technologies on the Web drawing on bibliometric and informetric approaches.” Fig. 1 illustrates the relation among the different “metrics.”

There is some confusion regarding terminology. Egghe,^[7] for example, provides a similar definition, but he does not differentiate between *cybermetrics* (study of information from *all* Internet applications) and *webometrics* (study of information from the World Wide Web only): *informetrics* is “the broad term comprising all-metrics studies related to information science, including bibliometrics (bibliographies, libraries,...), scientometrics (science policy, citation analysis, research evaluation,...), webometrics (metrics of the web, the Internet, or other social networks such as citation or collaboration networks),...” Glänzel and Schoefflin^[8] use the term *bibliometrics* as a synonym for bibliometrics, informetrics, scientometrics, and technometrics, and at the same time claim that these subdisciplines are not interlinked. In their view, bibliometrics as a field “includes all quantitative aspects and models of science communication, storage, dissemination, and retrieval of scientific information,” i.e., they limit the scope of *bibliometrics* to scientific information. The professional society of informetricians is ISSI, the International Society for Scientometrics and Informetrics, whose mission is to “to encourage communication and exchange of professional

Fig. 1 The relationships between the LIS fields of infor-/biblio-/sciento-/cyber-/webo-/metrics. Sizes of the overlapping ellipses are made for the sake of clarity only.

Source: From Small-world link structures across an academic web space: A library and information science approach, by L. Björneborn. PhD dissertation, Royal School of Library and Information Science, Copenhagen, Denmark, xxxvi, 399, 2004.^[6]

information in the field of scientometrics and informetrics.”^[9] From the mission statement we understand that scientometrics is not considered to be a subfield of informetrics, and there is no indication to the relation of bibliometrics to these two fields. The society does not limit the scope of these fields to scientific information only.

Hood and Wilson^[10] provide a detailed discussion on the use of the different terminologies, their origin and relative popularity in the Information Science subset of databases of DIALOG as of 2000. At that time *bibliometrics* was by far the most popular term, followed by *scientometrics* and *informetrics*. *Webometrics* and *cybermetrics* were not included in their searches. We submitted a variant of some of their searches on September 6, 2008 using

- ISI Web of Science (by Thomson Reuters)—searching for topics, which include title, abstract, author keywords, and keywords plus (keywords assigned based on the reference list), coverage from 1965 and onward
- Scopus (by Elsevier)—the searches were conducted in title and abstract. Keywords in Scopus are assigned both by the authors and by the database, and bibliometrics is one of the database-assigned keywords, therefore keywords were excluded from this search; coverage from 1996 and onward
- Google Scholar—a freely available bibliographic database with unspecified coverage both in terms of time

span and in terms of publications. Here the search term can appear in any part of the publication (depending on what is indexed by Google Scholar)

- Google—currently, the most popular Web search engine indexing Web pages and not necessarily scholarly publications
- Yahoo—currently, the second most popular Web search engine indexing Web pages and not necessarily scholarly publications

The results are presented in Table 1. The numbers of course are not comparable, since the search conditions in the different databases were not identical. Still we see that like in 2000,^[10] in each database the term *bibliometrics* was the most frequent, but the rank order of the other terms varied.

Hood and Wilson state that, the term *bibliometrics* according to most sources was coined by Pritchard^[11] in 1969; however, both Hood and Wilson^[10] and Rousseau (See the entry, “Informetric Laws,” p. 2747) mention a much earlier use of the French term *bibliometrie* by Otlet 1934. *Scientometrics* is the translation of the Russian term “naukometriya,” coined by Nalimov and Mulchenko in 1969. The term *informetrics* comes from the German word “informetrie” and was first proposed by Nacke^[12] in 1979. The term *webometrics* was introduced by Almind and Ingwersen^[13] in 1997. The origin of the term *cybermetrics* is not clear. It should probably be attributed to Isidro Aguillo, the editor of the e-journal *Cybermetrics* (<http://www.cindoc.csic.es/cybermetrics/cybermetrics.html>), founded in 1997.

GENERAL OVERVIEW

The literature related to informetrics is very extensive; in this section we list some review and encyclopedia entries and books on the topic. These references can serve the interested readers as starting points for exploring informetrics.

There are several reviews of *informetrics* and its subfields, including a number of review articles in the Annual Review of Information Science and Technology: the 1989 review by White and McCain of bibliometrics,^[14] a review of informetrics by Wilson in 2001,^[15] the 2001 review of scholarly communication and informetrics by Borgman and Furner,^[16] and a review of webometrics by Thelwall,

Table 1 Relative popularity of the “informetrics family” terminology. The number in brackets in each cell is the rank order of the term in the specific database.

Search term	Web of Science; 1965–	Scopus 1996–	Google Scholar	Google	Yahoo
Informetrics	86 ^[3]	98 ^[3]	3330 ^[3]	62,300 ^[5]	164,000 ^[5]
Bibliometrics	360 ^[1]	284 ^[1]	78,000 ^[1]	1,320,000 ^[1]	846,000 ^[1]
Scientometrics	164 ^[2]	216 ^[2]	13,100 ^[2] (incl. the journal by this name)	164,000 ^[3]	447,000 ^[2]
Cybermetrics	11 ^[5]	12 ^[5]	1250 ^[4] (incl. the journal by this name)	149,000 ^[4]	200,000 ^[4]
Webometrics	62 ^[4]	37 ^[4]	1160 ^[5]	253,000 ^[2]	414,000 ^[3]

Vaughan and Björneborn^[17] in 2005. Most recently Bar-Ilan^[18] published an updated review of informetrics, covering the literature published between 2000 and 2005.

The *Encyclopedia of Library and Information Sciences* also contains several articles related to *informetrics*, please see topical contents list. Russell and Rousseau^[19] discuss bibliometrics and institutional evaluation in the *Encyclopedia of Life Support Systems*' section on science and technology policy.

To this day there is only one textbook dedicated to informetrics, the book written by Egghe and Rousseau.^[20] The full text of the book is available online at <http://eprints.rclis.org/archive/00003297/>. There are a number of additional monographs on informetric topics, including Garfield's book on citation indexing;^[21] Cronin's book on the citation process;^[22] Moed's recent book^[23] on the use of citation analysis in research evaluation; and Thelwall's^[24] book on link analysis, one of the major topics in webometrics.

In order to identify the major journals related broadly to *informetrics*, Wilson^[15] ran the query bibliometric? OR informetric? in 11 databases using DIALOG. Here we ran the query bibliometric OR bibliometrics OR informetric OR Informetrics OR scientometric OR scientometrics OR webometric OR webometrics OR cybermetric OR cybermetrics on the currently existing two major, comprehensive commercial bibliographical databases, ISI's Web of Science (by Thomson Reuters) and Scopus (by Elsevier). Note that in Bar-Ilan,^[18] a much more detailed query was executed on the same databases. The publication year in both databases was limited to 1996 and onward, because Scopus' comprehensive coverage is from 1996 and onward. The journals producing the largest number of items for both databases are displayed in Table 2. Note that there are major differences in the two databases for the ranking of some of the journals. The major reason for this is that Scopus adds keywords, and bibliometrics is one of the keywords used, while WOS indexes only author-assigned keywords and what are called "Keywords Plus": keywords generated from the titles of the references. Many of the articles indexed by Scopus as "bibliometrics" are short items (e.g., letters) in *Nature*. These do not have abstracts, but deal with issues like the impact factor (IF) and citation analysis in general. The query terms do not appear in the title; thus, they are not retrieved by WOS, but these publications are definitely related to informetrics, and are picked up by Scopus because the keyword bibliometrics was assigned to them. In some cases, Scopus retrieves fewer items, than WOS—a paper-by-paper comparison of the two sets reveals that there are some differences between the two sets as a result of the use of the keywords and index terms in WOS, the index keywords in Scopus and the different indexing policies between the two databases regarding book reviews.

The results show that there is a wide interest in the topic, as papers appear both in general science journals

Table 2 Top journals related to informetrics, 1996–2008 based on documents retrieved for the query "bibliometric OR bibliometrics OR informetric OR Informetrics OR scientometric OR scientometrics OR webometric OR webometrics OR cybermetric OR cybermetrics" from WOS and Scopus. For both databases, the 10 most productive journals for the query are ranked and displayed.

Journal Name	Rank in Web of Science (number of documents in journal in parenthesis)	Rank in Scopus (number of documents in journal in parenthesis)
<i>Scientometrics</i>	1 (522)	1 (447)
<i>Journal of the American Society for Information Science and Technology</i>	2 (103)	3 (80)
<i>Information Processing & Management</i>	3–4 (42)	5–6 (39)
<i>Journal of Information Science</i>	3–4 (42)	7 (38)
<i>Research Evaluation</i>	5 (39)	4 (46)
<i>Journal of the American Society for Information Science</i>	6 (35)	9 (24)
<i>Research Policy</i>	7 (31)	8 (26)

<i>Current Science</i>	9–10 (18)	29–33 (13)
<i>Medicina Clinica</i>	9–10 (18)	10–12 (23)
<i>Journal of Informetrics</i>	11–12 (16)	10–12 (23)
<i>Nature</i>	165–519 (1)	2 (103)
<i>Journal of the Medical Library Association</i>	19–22 (9)	5–6 (39)

(e.g., *Nature*), in major information science journals (e.g., *JASIST*) and in specialist journals (e.g., *Scientometrics*). In addition to the specialist journals in the area; *Scientometrics*, *Journal of Informetrics*, *Research Policy*, *Research Evaluation*, and *Cybermetrics*, there are several conference series covering informetrics: the Biannual International Informetrics and Scientometrics Conferences of the International Society for Informetrics and Scientometrics (ISSI—<http://www.issi-society.info/>), the Biannual International Conferences on Science and Technology Indicators and the newly established International Conferences on Webometrics, Informetrics and Scientometrics of the COLLNET Research Network (<http://www.collnet.de>). Note that while *Scientometrics* was started in 1978, the *Journal of Informetrics* is a brand new journal; its first volume appeared in 2007.

OVERVIEW OF THE MAJOR INFORMETRIC TOPICS

Citation Studies

As Wilson^[15] claims: "[p]erhaps the largest subfield of informetrics is citation analysis or citation studies." First we need to clarify the difference between citations and

references, because in many cases there is some confusion between the two. We use here the terminology proposed by Price:^[25] “if Paper R contains a bibliographic footnote using and describing Paper C, then R contains a reference to C, and C has a citation from R. The number of references a paper has is measured by the number of items in its bibliography as endnotes, footnotes, etc., while the number of citations a paper has is found by looking it up [in a] citation index and seeing how many others papers mention it.”

Until 2004 there was only a single source for conducting citation studies: ISI's citation indexes: the Science Citation Index (SCI), the Social Sciences Citation Index (SSCI) and the Arts and Humanities Citation Index (A&HCI). These three indexes are accessible now as a single index through the Web of Science tab of Thomson Reuters' Web of Knowledge (<http://apps.isiknowledge.com>). ISI, the Institute of Scientific Information (now owned by Thomson Reuter), was founded by Eugene Garfield. Thus an excellent starting point to understanding citation theory and citation indexing is Eugene Garfield's book^[25] and his Web site (<http://www.garfield.library.upenn.edu/>) containing links and full texts of many works related to the topic. A detailed discussion of “citation cultures” can be found in Paul Wouters' Ph.D. thesis.^[26]

Why should we study and count citations? The basic assumption is that a scientific paper refers to other items because they are relevant to the current study; for example, they provide background, the current paper uses methods described in the referred paper, the current study is comparable/superior to other studies. For a detailed discussion of citation motivations the reader is referred to (pp. 28–30).^[22] To sum up, the basic assumption is that document A refers to document B for positive reasons in the vast majority of the cases and acknowledges the work reported in B. Of course, a reference can be negative as well, but this is the exception and not the rule. If one accepts the above assumption, then citation counts reflect the influence of the paper on subsequent literature. In the scholarly community usually each citation is considered equal; however, citations can be weighted based on the “importance” of the citing document.^[27–29] The weighted approach was proposed by Pinski and Narin,^[30] and a similar method is applied in PageRank, Google's ranking algorithm.^[31]

Of course, there are opponents to the assumption that the influence of a document can be measured by the number of citations it receives. Some of the reasons for criticizing this approach include bias in choosing references, missing references to influential work, and errors in the reference lists.^[32]

The impact factor

One of the most controversial issues in the area of citation analysis is the impact factor (IF). The IF was introduced

by Garfield and Sher,^[33] and it serves as a measure of journal importance. The Journal Citation Reports (JCR) annually publishes the IFs of journals indexed by the ISI Science and Social Sciences Citation indexes. The IF of a journal is defined as the number of citations the articles published in the journal in years $x-1$ and $x-2$, received in year x , divided by the number of articles published in the journal in years $x-1$ and $x-2$. Thus, IF measures the average number of recent citations that an article in the journal receives.

The IF is often misused when it serves as a proxy for the “importance” of articles published in the journal.^[34] Sometimes, articles in a high impact journal are not cited at all, and on the other hand some articles in low impact journals are cited heavily.

Citation practices differ greatly among disciplines,^[35] for example in the JCR category *Medicine, General & Internal*, the highest ranking journal in the list for 2007, *The New England Journal of Medicine* has an IF of 52.589, while the highest ranking journal in the category Information and Library Science, is *MIS Quarterly* with an IF of 5.826. The above example shows that IFs are not comparable across disciplines. In order to compare citation count and IF, the data have to be normalized.^[36–38]

h-index

A newly-introduced indicator to measure scientists is the h-index^[39] proposed by Hirsch. A scientist has h-index h , if he/she published h papers that have been cited h times or more, while all his/her other papers have been cited h times or less. Thus the h-index is a single measure that combines productivity and citation counts. The h-index is dependent on the data source used for collecting information on production and citations,^[40] on the time span used for calculating the index, the number of years the scientist has been active (biased against young scientists), and its characteristic values are discipline dependent. In spite of this, currently there is a huge interest in understanding and modeling the indicator^[41,42] and in proposing variants of the measure, e.g., the g-index proposed by Egghe.^[43] The g-index is the (unique) largest number such that when the articles are ordered by the decreasing number of citations, the top g articles receive (together) at least $g^{[2]}$ citations.

Citation databases

As pointed out above, until November 2004 there was only a single comprehensive source for carrying out citation studies—the ISI Citation Indexes. In November 2004, Elsevier launched Scopus (<http://www.scopus.com>) and Google launched (as a beta) its free service Google Scholar.

Google Scholar enables searching for scholarly literature and also provides citation counts of the items discovered by it. Google Scholar has unspecified coverage both

in terms of the indexed items and in terms of time-span. It has agreement with major publishers and also gathers information by crawling through the Web. Google Scholar was greeted by the scientific community with mixed feelings. For criticism about its performance, the reader is referred to some of the articles published by Jacso,^[44,45] and for more positive impressions the reader is referred to Harzing.^[46] Harzing developed an application called “Publish or Perish” (<http://www.harzing.com/pop.htm>) for carrying out informetric analyses based on Google Scholar data. Although the informetric community is currently quite ambivalent about Google Scholars, scientists, and students use it heavily, as can be seen from statistics provided in:^[47] 73% of the academic institutions examined in the study provided link resolution from Google Scholar results to their online resources.

Scopus is a bibliographical and citation database. It covers more publication sources than the Web of Science and is not limited to indexing journals but also includes some proceedings. The citation data only goes back to 1996, whereas the Web of Science has citation data from 1900 for Sciences, from 1956 for the Social Sciences and from 1975 for Arts and Humanities.^[48] As of September 2008, Scopus indexes 15,000 journal publications,^[49] as compared to 8700 indexed by the Web of Science. Journal indicators based on the Web of Science data are published in the Journal Citation Reports, and other country and discipline specific statistics are provided by the Essential Science Indicators. Freely accessible country and journal indicators based on Scopus data are available from the SciMago Research Group (<http://www.scimagojr.com/>). In October 2008 data from the ISI Proceedings Indexes were merged into the Web of Science.

Co-citation analysis

Co-citation measures the frequency with which two documents are cited together.^[50] Frequent co-citations are interpreted as similarity or co-occurrence of ideas. Co-citation analysis can reveal the core literature for a topic, and then map the structure of the topic.^[50,51] Co-citation analysis was independently introduced by Small^[54] and Marshakova.^[52] Later co-citation analysis was extended to author,^[53–55] and journal co-citation analyses.^[56] Mapping based on co-citation matrices is only one of several available techniques. In the section on visualization, we mention additional data sources for visualization like citation matrices, co-authorship data, and co-word analysis.

Open access

Open access is defined as “free, immediate, permanent, full-text, online access, for any user, web-wide, to digital scientific and scholarly material.”^[57] An interesting question regarding open access publications is whether free access to publications increases the publication’s citation

impact. Several studies showed that electronic access (even if the access is not free) increases citation counts (e.g., Lawrence^[58] and Harnad);^[59] however, some studies (e.g., Anderson)^[60] reached a different conclusion. There are several possible reasons for increased citation counts, including early access (papers are online even before the refereeing process is over), selection bias (authors prefer to publish online their “better” papers), and the ease of access, called the “open access advantage.”^[61] Moed^[62] examined these effects on two sample data sets from Arxiv, a huge open access e-print archive containing nearly half a million e-prints as of September 2008, and found no sign of open access advantage. A similar conclusion was reached by Craig et al.^[63] Harnad^[64] advocates institutional repositories for self-archiving and open access, and promotes mandating archiving of publications in institutional repositories to ease access to scientific publications.

Theoretical Informetrics

There are three famous regularities or informetric laws: Lotka’s law, Zipf’s law, and Bradford’s law.^[15] Lotka’s law^[65] is an inverse square law between the number of authors of scientific papers and the number of publications of each author. According to this law, the number of authors producing two items is about one-fourth of the number of authors producing a single item, and the number of authors producing three items is about one-ninth of those producing a single item, and about 60% of all authors contribute a single item only.

Zipf’s law^[66] has a similar flavor, but instead of authors and publications, it relates to the rank order and the frequency of words in texts. The rank order of a word in a text is the placement of the word in a list sorted in decreasing order of frequency in the text. The law says that if the words in the text are listed in decreasing frequency, then the rank of the word in the list times its frequency in the text is a constant.

Bradford’s law^[67] is called Bradford’s law of scattering, and describes the scatter of scientific literature. He listed the publication sources (e.g., journals) on a specific topic in decreasing order of productivity (productivity is assessed by the number of items on the topic published by the publication source) and partitioned the ordered list into three equal size sets in terms of the number of publications, and showed that the ratio between the number of publication sources in the three zones is about 1: n : n^2 ; i.e., a small number of publication sources (called the “core”) produce a considerable fraction of the publications.

Extensive discussions of informetric laws can be found in additional ELIS entries (see the Topical Table of Contents). These laws are also discussed in the informetrics textbook^[20] and the ARIST review on informetrics.^[15] Egghe recently published a book^[68] where all informetric laws are described in terms of

appropriate Lotkaian functions, thus producing a unified theory based on Lotkaian informetrics.

In addition to studying informetric laws and distributions, the theory of informetrics is also concerned with other issues including modeling growth processes. It should be noted that besides the growth of the scientific literature, older items are usually cited less—they become “aged” and sometimes even obsolete. Well-known, applicable growth models are so-called rich-get-richer models, also known as preferential attachment,^[69] or cumulative advantage.^[70] Examples of such models and studies include works on the evolution of coauthorship networks.^[71,72] Börner, Maru, and Goldstone^[73] proposed a model where both author and paper networks evolve simultaneously. Visualizations of evolving networks are discussed in the next section.

Mapping and Visualization

Many informetric results call for visualization. We have previously seen examples of co-citation analyses that model the structure of scientific topics. Collaboration networks are also best understood through visualization, and visualization techniques also help in gaining insights into evolutionary processes. Here we provide only a number of examples of visualizations. Excellent starting points for exploring the topic are the recent ARIST review on visualization^[74] and Chen’s book on mapping scientific frontiers.^[75] Several studies of citation patterns between journals visualized the resulting structures.^[76–78] Garfield^[79] developed algorithmic historiography that allows studying the origins of a topic and its development over time, and the resulting visualization is called a “historiograph.” Glänzel^[80] studied and mapped coauthorship relations between countries. Maps can also be created based on co-word analysis, i.e., on co-occurrence of words.^[81]

Cybermetrics and Webometrics

Cybermetrics and webometrics are the newest subfields of informetrics. The first webometric/cybermetric studies conducted in the late 1990s showed the applicability of informetric techniques for the Internet in general and specifically for the World Wide Web.^[82–84] Ingwersen^[85] defined the Web Impact Factor (WIF), which corresponds to the Journal Impact Factor, where instead of citations; links pointing to the Web site are counted. More precisely the WIF is the number of pages with links pointing to the given site divided by the number of Web pages in the site. Note that Egghe^[86] warned against drawing a direct analogy between citations and links. Ingwersen used a Web search engine to collect both the number of links and the number of Web pages. However, Web search engines are not very reliable and their coverage of the World Wide Web is far from being

even.^[87–90] Problems of search engine reliability are far from being solved, as can be seen in.^[91]

One way to overcome the problem of search engine reliability is not to use them for data collection, but to use a Web crawler instead. Thelwall developed such a crawler (available from <http://socscibot.wlv.ac.uk/>) and studied extensively the link structure between U.K. universities (for a summary of this work see Thelwall).^[24] He also developed several variants of the WIF that correlated better with actual research performance.

Similarly to the study of citation motivation, it is of interest to understand why academics are mentioned on Web pages^[92] and why links to pages on academic Web sites are created.^[93] Bar-Ilan^[94] created a framework for classifying links between academic sites and applied it to links between Israeli academic Web sites.

Most studies of inlinks to academic Web sites from other academic Web sites found strong correlation between the number of inlinks and research performance. A natural question is whether there is a similar correlation between the number of inlinks to a journal Web site and its IF. Vaughan and colleagues^[95,96] found such a correlation both for LIS and law journals. Link structure of commercial Web sites has been studied as well. In a number of studies carried out by Vaughan,^[97,98] significant correlation was found between the business performance and the number of inlinks.

Vaughan and Shaw^[99] introduced the concept of “Web citation,” which is roughly an appearance of the title of a publication within a Web page (not necessarily as a link). They found good correlation between the number of “regular” citations and the number of “Web citations” in a number of disciplines. Kousha and Thelwall^[100] examined so-called Web/URL citations, where a “Web/URL citation of an online journal article is a Web mention of its title, URL, or both” for a number of disciplines. For all disciplines except psychology they found good correlations between Web of Science citation counts, Google Scholar citation counts and Web/URL citation counts.

Just as the growth and evolution of scientific topics are studied, the evolution of the Web is also a topic of interest for webometrics. Several longitudinal studies were carried out in the webometric context. Scharnhorst and Wouters^[101] proposed a classification of temporal changes that occur to the web graph. Koehler^[102] studied the changes that occurred to a fixed set of pages over time. Bar-Ilan and Peritz^[103] carried out an eight-year study following the evolution of the pages containing the search term “informetrics” on the Web. They showed that besides growth; disappearance and changes to the content of Web pages are nonnegligible processes as well. Disappearance can also be demonstrated by testing URL references in scientific publications.^[104]

More recently there are also webometric studies of Web 2.0, including studies of blogs,^[105] of tagging systems,^[106] and of social networks like Myspace.^[107] With

the widespread use of Web 2.0 technologies, more studies in this direction can be expected in the future.

Research Evaluation

Scientometrics, as defined in the introduction is the study of the quantitative aspects of science. Scientometric studies serve as tools for research policy makers and also help in the evaluation process. Historical aspects of measurement and statistics of science and technology are discussed by Godin.^[108] Etzkowitz and Leydesdorff^[109,110] model the interaction between government, industry, and universities as the “triple helix” for explaining the research system. The recently published *Handbook of Quantitative Science and Technology Research*^[111] provides a state-of-the-art survey of research in this area. What can be evaluated using scientometric techniques? Here we bring examples of evaluations of individual researchers, research units, universities, journals, and countries.

Individual researchers can be evaluated based on their productivity (number of publications), patents, funding, citation counts, the IFs of journals they publish in, and peer review. One of the more interesting questions is how much agreement there is between the quantitative, scientometric measures and peer review. There is a lively debate around this issue in the context of the U.K. Research Assessment Exercise (RAE). Until the 2008 exercise, the distribution of funding for the U.K. universities was decided based on peer review only. In the current exercise, both peer review and bibliometric indicators are considered. Norris and Oppenheim^[112] found high and significant correlations between RAE rankings and rankings based on citation counts for archeology. Weingart^[113] warns that when bibliometric indicators are used for research evaluation, the results can be manipulated. An interesting example of this is Australian science, where funding is mainly based on the number of publications, as a result of which Australia's share of publication increased by 25% between 1988 and 1997, while its citation impact decreased.^[114]

Thus one question is whether to employ peer review or to rely on indicators. Another question is which indicators to use. To illustrate this point, Cronin and Shaw^[115] compared rankings based on citation counts, Web hits, and media mentions. The resulting rankings were considerably different. The data source for computing the indicators is also of importance.^[116]

Also of interest are rankings of universities. There are several rankings, the best known are the Shanghai rankings (<http://www.arwu.org/>) and the rankings produced for the *Times of London* Higher Education Supplement (<http://www.timeshighereducation.co.uk/>). Both these rankings take into account some bibliometric data, but include nonbibliometric measures as well. There are also rankings based on webometric data (<http://www.webometrics.info/>) and also rankings based on pure bibliometric data (<http://www.cwts.nl/cwts/LeidenRankingWebSite.html>). There

are several Leiden rankings demonstrating the variability of the results according to the chosen indicator(s).

When considering the world of science, policy makers are often interested in comparing countries. For example, King^[117] calculated the scientific impact of nations, based on publications counts, citation counts, share of top 1% papers, GDP, normalized citation counts, and financial inputs. The findings indicate that the share of United States is declining and the EU countries are catching up. Glänzel, Schubert, and Braun^[118] studied the productivity and citation impact of the 32 most prolific countries based on ISI data for the years 1990–1998. Zhou and Leydesdorff^[119] concluded that China has become the fifth leading nation in terms of scientific productivity based on data from the Web of Science as of 2004.

Scientometric indicators have considerable weight in decisions regarding the funding and development of science. As can be seen from the above-mentioned studies, there does not exist one “correct” or “perfect” method or indicator for evaluation, but informetricians continue to search for better quantitative indicators for evaluating and forecasting science.

SUMMARY

In this entry, we tried to provide an overview of informetrics and its subfields. It is impossible to cover all areas of interest in the field in such an entry. However, we hope that the interested reader will consult some of the sources mentioned in the references in order to deepen his/her knowledge of the topic.

Institutional Records and Archives

David Farneth

Special Collections and Institutional Records, Getty Research Institute, Los Angeles, California, U.S.A.

Abstract

Modern organizations are exploring holistic approaches to managing records, information, and knowledge. The value and use of institutional records are optimized when records management and archival activities are coordinated and closely aligned according to a common set of goals and principles. Integration of records management and archives functions, along with the adoption of newer conceptual models for managing the life cycle of institutional records, have led to revised methods and best practices. Archival processes for “in-house” records may diverge in some ways from those for collecting repositories. Information professionals are expanding their roles and working collaboratively to manage and preserve electronic records. Societal attitudes about transparency and free access to information are changing the ways that institutions think about their information assets.

INTRODUCTION

As modern organizations become more flexible and managed more laterally, institutions are exploring holistic approaches to managing records, information, and knowledge. Improved conceptual models for managing the life cycle of institutional records are prompting information professionals to expand their roles and to work collaboratively across their organizations. At the same time, new technology solutions designed to manage and preserve electronic records are moving from the planning phase to implementation. Most recently, changing societal attitudes about transparency and free access to information are influencing the ways that institutions think about their information assets. All of these factors are prompting institutional archivists and records managers to find new ways to collaborate and integrate their programs in ways that will better serve their institutions’ goals and mission. This new form of information professional—the archivist-records manager—must develop skills that are not yet routinely covered in many graduate program curricula.

Records management and institutional archives programs are key components in managing the operational, program-specific, and administrative records of active, modern organizations. Contrary to traditional practice, many institutions now believe that the value and use of institutional records are optimized when records management and archival activities are coordinated and closely aligned according to a common set of goals and principles. Using this perspective as a point of departure, the entry provides a summary of the key concepts that inform traditional and newer approaches to managing the life cycle of modern records and highlights ways in which archival processes for “in-house” records may differ from those of

collecting repositories. The focus is on managing the records themselves, rather than the administrative strategies required to establish, staff, fund, and sustain the different types of programs and repositories that fall under the general rubric of institutional or “in-house” archives, such as business archives, museum archives, hospital archives, university archives, etc. Also excluded are discussions of the types of records specific to these repositories (for example, the exhibition-related records typically found in a museum’s archives, or grant-giving records found in a philanthropic organization’s archives). Readers are encouraged to explore more detailed texts about the concepts and standards introduced herein.

The specific topics cover a range of concepts and activities associated with integrated management of institutional records: institutional context, the value of institutional records, conceptual models, appraisal and selection of records, archival arrangement and description, research access to institutional records, and integration of records management and archival functions. The entry concludes with a look at institutional records in the broader information environment and a gloss on some of the issues associated with managing electronic records, which arguably now comprise the most important records produced in modern organizations.

INSTITUTIONAL CONTEXT

An understanding of the nature and value of an institution’s operational and administrative records may be gained through a careful and systematic analysis of the organization’s mission and activities. Both records managers and institutional archivists benefit from this activity

Table 1 Techniques for organizational analysis

To gain an understanding of . . .	. . . these analytical techniques can be used
The wider world in which the organization operates, including the legal and regulatory framework	Environmental analysis
What the organization does and how it carries out its work	Systems analysis, functional analysis, process analysis
The formal structure of the organization, and its values, beliefs, and attitudes	Cultural typology, structural analysis
Existing procedures for creating, maintaining, and using records	Process analysis, records survey
The nature and extent of records	Records survey

Source: Shepherd, E.; Yeo, G. *Managing Records: A Handbook of Principles and Practice*; Facet: London, U.K., 2003; 31.^[1]

because it supports the kind of functional analysis that is central to many of the current trends for managing both paper and electronic records.

Elizabeth Shepherd and Geoffrey Yeo have articulated why an organizational analysis contributes to records management objectives: “(R)ecords managers must analyze the role and responsibilities of the organization, study its structures and working methods, and discover how these have changed during its life. They also need to identify the broader issues that influence the way the organization operates, including its corporate culture and the interests and expectations of stakeholders within the organization and externally.”^[1] They have also compiled a list of analytical techniques for undertaking an organizational analysis (Table 1). The National Library of Australia has published a guide for undertaking an institutional analysis in its highly influential *Designing and Implementing Recordkeeping Systems (DIRKS) Manual* (part two, steps A and B).^[2]

VALUE OF INSTITUTIONAL RECORDS

As a society we value the achievements of prominent and creative individuals, and, as a result, their archives are regularly acquired by special collections and manuscripts repositories. But significant cultural advancements also take place within organizational environments. Therefore, the records of organizations, too, explain and illuminate some of mankind’s greatest achievements.

Value of Institutional Records

The value of institutional records to society and to the parent organization is complex and intertwined (Table 2). Active use of institutional records stimulates institutional memory, preserves knowledge and intellectual property, improves accountability, and provides the larger

Table 2 Value of institutional records

Societal benefits	Contributes to education and the creation of new knowledge Preserves records needed for historical and other research Documents contributions to society Protects legal rights of institutions and individuals Protects ownership of property Documents place and identity in modern society
Business uses	Strategic planning and decision-making Communications, both internal and external Accountability and compliance Organizational continuity Preservation of intellectual property and information assets Protection of legal rights and assets Public relations and advertising Finance Research and development Repository of corporate culture and memory Evidence achievements (both corporate and individual) Evidence of place and identity in modern society

The evolving role of in-house business archives: from tradition to flexibility. In *The Records of American Business*; O’Toole, J. M., Ed.; Society of American Archivists: Chicago, IL, 1997; 41–55.

community with a broad historical focus on the organization’s evolution and role in society. The business uses are diverse, ranging from strategic planning to leveraging existing knowledge to documenting achievements. Whether institutional archives are used to document the history of a specific institution, or to enable a scholar to understand important historical trends and events, or to inform individuals of the reasons for certain occurrences in his or her local community, they are vital to a society and its inhabitants.

Categories of Records

Institutional records are often divided into two categories: administrative records and program (or operational) records. These distinctions become important for managing retention of the records and for determining archival value.

An administrative record is “a document that has been preserved because it facilitates the operations and management of an agency, but which does not relate directly to programs that help the agency achieve its mission.”^[3] Administrative records often have shorter retention periods governed by a specific section of the retention schedule. They typically support functions related to

scheduling, coordination of activities, logistics, and lower-level reporting.

Program records “relate to the substantive activities an organization undertakes to accomplish its mission or mandate.”^[4] They typically will have longer retention periods and longer-term value to the organization.

A subset of institutional records may also be defined as vital records that are needed to recover business operations after a disaster or those that “protect the assets, obligations, and resources of the organization, as well as its employees and customers or citizens.” They may also document the delegation of authority and lines of succession.^[5]

CONCEPTUAL MODELS

Institutional records are usually managed through a combination of records management and archival processes. Some of the goals and objectives of these two disciplines are shared, while others are not, leading to professional and operational tensions that may be challenging to resolve.

Life-cycle Concept

Traditionally, records management has been more oriented toward the efficient management of large quantities of records in support of current business operations, while archival programs have focused on preserving permanent records that document organizational history and memory. The records life-cycle concept first introduced by T.R. Schellenberg in 1956 reinforces this division by postulating that records go through a number of distinct

phases: creation, capture, storage and maintenance, use, and disposition. When records reach the disposition phase they are either destroyed or transferred to an institutional archive for permanent retention and preservation. The various attempts at modeling this concept have shown it to be a linear or circular progression, often related to the physical location and care given to paper records. Best practices in both the records management and the archives communities developed around each of the phases of the life cycle. Records management units managed the records during their active and inactive phases, and archives units took charge of the records when their business value was diminished and they were no longer actively used by the organization.^[6]

Continuum Concept

As organizations adopted new, more flexible management structures, and as the challenges of managing electronic records began to be identified and analyzed, the life-cycle concept became unworkable. The structure of electronic records is more logical than physical. Archivists and records managers agreed that records could serve many uses at the same time. The continuum concept (Fig. 1) was therefore developed in the 1980s and 1990s to show that managing records was actually a continuous process in which various elements passed “seamlessly into another.”^[7] Rather than being time-based, the continuum concept recognizes that there are different perspectives to managing records operating at the same time. Records that support current business operations may simultaneously be used to document organizational and collective memory.

Fig. 1 Records continuum model.

APPRAISAL AND SELECTION OF RECORDS

Appraisal is a core activity in both records management and archives management, and it is often thought of as the essence of both professions.

In records management, “appraisal is the process by which an organization identifies its requirements for maintaining records.”^[8] In archives management, appraisal is “the process of determining whether records and other materials have permanent (archival) value.”^[9] Some recent writings on archival appraisal have preferred the term “selection” over “appraisal.”

Appraisal in both contexts is complex and difficult, and a large body of literature is devoted to it. This section will simply introduce concepts and issues related to appraisal that have most relevance to institutional records. Readers are encouraged to consult the sources listed in the bibliography and related entries in this encyclopedia for more comprehensive information.

Records Management Appraisal

In records management, appraisal refers to the often lengthy, complex, and reiterative three-step process required to develop and implement records retention procedures. It is comprised of:

1. Analyzing an organization’s records to determine the proper retention period based on primary values (administrative, fiscal, and legal) and secondary values (evidential and informational).
2. Documenting a retention policy, usually in the form of a records retention schedule.
3. Reviewing, updating, and maintaining the policy.^[10]

Records appraisal is an ongoing activity even after a retention policy is developed and adopted. Newly created records must be classified according to the policy, and new records series may be required as the organization changes. The policy may also be applied to “legacy” records that were created before the policy was adopted. Records creators and records managers continuously make decisions about which records need to be created, how they should be captured in a record-keeping system, how they should be classified for retention, and which ones need special handling for preservation or security.

Archival Appraisal and Selection

The selection of records to be preserved in an institutional archives usually flows from the mission of the individual repository. These selection activities usually focus inward, with a goal of documenting the parent organization. The mission of an institutional archive may articulate several goals, for example: to support accountability, to capture

history, and/or to preserve products and intellectual property. Appraisal decisions will therefore support the defined mandates. Archivists usually also have guidelines for the level of detail desired, or may make selection decisions based on the person or business function that created the records.

Some institutional archives are also “collecting repositories” that accept materials from external sources. For instance, they may collect the family papers of the organization’s founder or attempt to document the reputation and societal impact of the organization as reflected in external publications and media coverage. They may also attempt to document particular research topics related to the organization’s core mission. For instance, the archives of a philanthropic organization may decide to select and acquire materials related to the history of philanthropy.

Traditional appraisal methodologies analyze the content of records, while newer methodologies focus on the context in which the records were created. The methodology selected by an individual repository will, again, be determined by its mission. Repositories with a historical, informational approach may prefer the traditional approaches. Those focused on evidence and accountability, and those that have large volumes of records to manage, will probably prefer the contextual approach. In practice, however, many institutional repositories have hybrid missions and often choose to rely on a combination of both approaches.

Value based on content

Schellenberg’s seminal approach to American archival appraisal defined the primary and secondary values of records. He believed that records should be selected for archival preservation only after their operational value had ceased. Then, only those records that had evidential or informational value that would support historical and other scholarly research should be preserved. Traditional methodologies based on Schellenberg’s model require the archivist to examine the content of the records to determine their value. This traditional approach is often called “bottom-up” appraisal.^[11]

Value based on context

As the bulk of modern-day records increased and more records were created and stored electronically, archival theorists recognized that a new approach was needed that did not require the time-intensive task of inspecting all records. David Bearman, in particular, proposed reverting to provenance as the basis for selection and refined a method of selection based on records functions.^[12] From this approach evolved selection processes based on the record continuum approach. Canadian archivists were particularly attracted by the functional approach. Terry Cook

defined a “macro-appraisal” (or “top-down”) approach based on the function of the records creator, which, in turn led to refinements in functional analysis that emphasized context over content.^[13] American archivist Helen Samuels has applied a functional analysis to university records, and her study has made a strong case for applying this methodology to the records of any type of organization.^[14]

Christopher Baer has drawn on both traditional and newer approaches to develop a model for appraising business records that considers four parameters: the business strategy of the organization, the structure of the organization, the level of informational detail provided in the record, and the elemental purpose and activities (i.e., “function”) supported by the records. This more hybrid approach takes into account both the context and content of records.^[15]

ARCHIVAL ARRANGEMENT AND DESCRIPTION

Most national and international content standards for archival description cover both corporate records and personal papers (Table 3). Working within these frameworks, archivists in active organizations have a unique opportunity to emphasize information about the context, function, and purpose of records, which, in turn, adds inestimable layers of complexity to their meaning.^[16]

- Who created the record (which department and which person of what status within the department)
- Why the record was created (for what administrative purpose)
- What form the record has (minute book, file of correspondence, etc.)
- How it can be found and accessed

- How it relates to other records (whether there are likely to be more records on the same subject somewhere else)
- When and why were related records destroyed

The arrangement of institutional records according to provenance is particularly important to the researcher for determining point of view and analyzing biases (For instance, correspondence between two mid-level managers about a particular event may be much more revealing than a press release about the same event.). It is also important to know why the records were created, how the records were kept, and what functions and activities they supported.

Arrangement and description of collections that come into collecting archives is relatively straightforward, because each new acquisition usually represents a discrete and independent unit that can be arranged, described, and stored without reference to direct or integral connections to other collections in the repository. Record groups and record series are based solely on the records themselves. Each collection is usually described by its own finding aid.

Records that enter an institutional archives have fundamentally different characteristics, both in the way that they enter the repository and how they have to be arranged and described. Even though archivists strive for the logical and orderly acquisition of new records according to the retention policy, records may also come to the repository in a less planned way, motivated by staff departures, the physical movement of offices, an upcoming anniversary, or the completion of major projects.

The record groups and record series in an institutional archives are usually based on provenance, which means that they will reflect, in part, the organizational structure of the organization. New acquisitions are usually described as additions to existing records series and groups. Many different accessions may be brought together intellectually in a single finding aid.

The systems that institutional archivists use to create and maintain descriptive information about their holdings will vary widely according to the type of organization, the degree of public access afforded to the collections, the amount of information technology support that is available, and the degree to which archivists are compelled to use existing systems rather than acquire new ones specific to archives management. The ideal systems for documenting information about archival collections accommodate many levels of hierarchy that can reflect the context and relationships of and between the records themselves. These systems might take the form of relational databases or they may use text encoding to maintain hierarchical relationships, such as with Encoded Archival Description.^[17] Library bibliographic systems do not provide enough levels of hierarchy to describe archival collections. (See the related entries “Archival Appraisal and Acquisition,” p. 120, and “Archival Arrangement and Description,” p. 130, for more detailed coverage.)

RESEARCH ACCESS TO INSTITUTIONAL RECORDS

While government archives must follow laws and mandates governing public access to information, the policies that determine access to information in institutional archives usually reflect the business nature of the organization and the level of security that is required to protect the organization’s interests. Many organizations have guidelines for handling sensitive information. Legal statutes protecting personal privacy, medical records, and student records also dictate types of information that should be kept confidential.^[18] Most organizations find it necessary to protect access to records related to attorney-client privilege, human resources, and those that contain business or trade secrets. Even nonprofit organizations have sensitive records related to sustaining the organization’s business.

In practice, most business and corporate archives do not exist to provide public access to their holdings. Other types of institutional archives, especially those associated with nonprofit and educational organizations, exist in large part to serve the public interest.

Most institutional archives hold records of interest to the staff of the creating organization, the general public, and the media, and attempts are made to provide the appropriate level of access to each of these groups while maintaining a suitable level of confidentiality and security.^[19] Some records were created for public distribution, and these are usually made available for research as soon as they enter the archives. For the most part, however, the records held by institutional archives were created for internal use, and public research access may be restricted to varying degrees. The policies controlling access may be directives communicated by the executive management of the organization or they may be entrusted to the archivist to determine.

Effective access policies for institutional records will include “clear description of restrictions, time limits on restrictions, procedures for determining restrictions, and a statement regarding lines of administrative authority.” The categories of restriction usually include “open,” “restricted” to staff, and “closed” to all except the office of origin. There is often a general period of restriction (for instance, 10–20 years) and then longer periods for records of extra sensitivity or those whose confidentiality is protected by statute. The policy should state when and how restrictions are placed on records and the lines of authority and procedures for obtaining access.^[20]

INTEGRATION OF RECORDS MANAGEMENT AND ARCHIVAL FUNCTIONS

Practical solutions do not always line up neatly with theoretical models. The goals and activities of records management and archival programs do not always neatly mesh, but their missions should align with the goal of

fostering efficient management of institutional records and leveraging their value. By working collaboratively, records managers and archivists identify areas of conflict and seek productive resolutions.

Records Retention and Archival Appraisal

When managing the records of an active organization, records managers must deal with records in large groups and are intent on destroying records according to policies that are designed, in part, to promote efficiency and to protect the organization. Archivists work to preserve a subset of records consistent with selection guidelines. Sometimes these two organizational goals come into conflict.

In theory, an organization's retention schedule should be a useful tool for guiding archival appraisal, but this is often not the case in practice. Modern-day retention schedules are designed with fewer categories (often called "big buckets") to promote ease of understanding and use. As a result, they usually do not provide enough detail to support archival appraisal. Function-based retention schedules are difficult to apply to unified files of correspondence, or project, case, and subject files, all of which might be of high interest to archivists. They also may not correlate easily with individual office file plans.

Retention schedules may be strongly tied to organizational structure, and retention policies are usually implemented through official departments. But the work in modern organizations is more fluid, with people and information traveling easily across departmental lines. While retention schedules may capture the official flow of documents, they often do not capture the real flow of information. In addition, compliance with retention schedules across a large organization is usually inconsistent, and often the records of the offices of senior executives are not scheduled. These situations lead to gaps in documentation and loss of records at the higher decision-making levels of the organization.^[21]

Because of these inherent tensions between records management and archival appraisal, some records professionals argue that these functions should be separated organizationally. Others contend that the tensions are best resolved by an integrated approach, because the logical road to conflict resolution is through dialogue and compromise, and this happens more easily when both records managers and archivists are members of the same team.

Records Managers and Archivists Working Together

Collaboration between records managers and archivists is becoming essential as more information professionals are recognizing that the continuum model is closer to reality than the life cycle model, especially in the digital age. Archivists should be proactive in bringing their

organizational and preservation skills to the process of records creation and the maintenance of active records, and capture copies of electronic records much earlier than they would paper records. Records managers should understand archival appraisal, be alert to records that meet the collecting policies of the institutional archives, and encourage the creation of authentic and reliable records that will document key organizational functions. Both groups should keep theoretical goals firmly in sight while remaining flexible in their respective areas of control and delivering a unified message to staff in the organization.

INSTITUTIONAL RECORDS IN THE BROADER INFORMATION ENVIRONMENT

The documentation of an institution exists in many forms and is cared for by many units across the organization. The value of institutional records can be leveraged through integrated access to information achieved through strong partnerships between many departments in the organization, including archives, records management, legal, communications, compliance, information technology, and business units. Institutional records can be key components of programs devoted to document management, information management, knowledge management, disaster recovery, digital asset management, intellectual property management (including institutional repositories), and preservation of electronically stored information (including trusted digital repositories).

The technological revolution is providing new opportunities for information integration and collaboration among information professionals. "In this new world of records, archivists must become more involved with records creation and maintenance. Managers, information managers, and systems managers must become more involved with records quality. Archivists, records managers, and information managers must work together to establish standards and procedures before electronic records become the primary media for maintaining the institutional memory."^[22] This prescient statement was published in 1993. Now, years later, information professionals are still grappling with the challenges of capturing and preserving electronic records. Many archivists fear that 25 years of key documentary evidence has been, or will be, lost.

THE CHALLENGE OF ELECTRONIC RECORDS

The amount of electronically stored information in organizations and businesses is growing exponentially. Managing electronic records across an organization is one of the most challenging tasks facing institutional information managers, and it is also the one most easy to ignore for institutions that do not have high risks associated with poor records management, that lack technological

expertise and infrastructure, or whose mission is focused on more traditional functions.

Electronic records are much more fragile and at risk of deterioration and loss than are paper records. Although the concept of the paperless office has yet to reach fruition—and may never do so—the importance and criticality of electronic records has evolved substantially in recent years. At first, most electronic records were considered to be transient; desktop computers were the tools used to prepare a record that was printed on paper and filed. Now, more often than not, the electronic document is considered to be the permanent record, and the paper copies are transient, used for ease of reference and then discarded.

Records managers and archivists have attempted to apply traditional methodologies to electronic records. While this task is challenging enough, it is complicated by quickly changing technological advancements, system and format obsolescence, and the need for new resources to support technology infrastructure, software acquisition and implementation, training, and sustainability. The problem of obsolescence applies to hardware, operating systems, software, file formats, and storage media. Different processes are evolving to address each.

Thousands of people in government, industry, and the academy are working on these problems, from creating conceptual models, to writing standards, to building technology solutions for implementing them, to solving technological obsolescence. National archives programs in the United States, United Kingdom, Australia, New Zealand, Canada, and the Netherlands (to single out just a few) are developing systems and processes to identify, capture, classify, describe, preserve, and provide appropriate access to electronic records. Various international, national, and local agencies are promulgating standards and best practices related to processes, metadata, and digital preservation (Table 3). The information management sector has developed suites of applications to manage electronically stored information, all with limited or mixed success, including systems for document management, digital asset management, content management, electronic record management, and e-mail “archiving.”

Records Management Context

The principal challenges of managing electronic records relate to the computer’s inability to classify records and activate event-driven retention policies. Most systems developed to date require the user to classify records, most often by dragging them into folders that emulate series on a retention schedule. Records managers have therefore been moving toward simplifying retention schedules and reducing the number of records series in an attempt to create systems that can realistically be learned and applied by the entire staff of an organization. Event-driven retention policies pose larger challenges because they usually

require a human to recognize that an event has happened before the retention period can be properly assigned.

Records managers working in collaboration with staff in information technology, legal, and business units have been devising new processes to manage three categories of electronic records: those created and retained in e-mail systems, those produced by enterprise database applications and managed by information technology teams (structured data), and those produced by desktop applications and managed by business units on workstations and shared network folders (unstructured data). Many records managers are experimenting with ways to leverage current technology and train staff in new procedures for managing electronic records according to established policy, including the distribution of directory structures that correspond to official records and training staff to associate more metadata with records created in desktop applications. Other more comprehensive strategies include auto-classification, applying retention rules to records in legacy systems, managing access based on privacy and security requirements, and building records management functionality into enterprise business applications.

Archives Context

Archival functions have been largely ignored by the emerging technologies developed for content management and records management, which have had difficulty appreciating the need for long-term digital preservation strategies and identifying a viable market. As a result, archivists tend to look to governments that have provided mandates and money for developing electronic records solutions, with the hope that systems designed for extraordinarily large repositories will be scalable to smaller ones.

The challenges associated with the archival management of electronic records are many and varied. Archivists are charged with preserving and providing access to authentic and reliable records over a long time (decades, if not centuries). Lacking expertise and resources to ensure long-term preservation and access, archivists have been hesitant to accept electronic records into their repositories.

Leaving aside technological and organizational cultural issues (such as lack of a pressing business need, lack of resources, and lack of motivation) the traditional functions of archival management—accession, appraisal, arrangement, description, access, and preservation—have traditionally required a large degree of human analysis. The continuum model and top-down appraisal methods have been helpful in explaining the archivist’s new role during records creation and in applying appraisal decisions without having to look at the individual records, but much work remains to develop suites of applications that can automate the full range of archival functions. How should computers apply macro-appraisal rules? What new metadata schemas are required? How can computers enhance

the records with value-added description? How will computers review records for appropriate access? These are just a few of the questions being explored.

Need for Collaboration

Successful institution-wide electronic records management requires close collaboration between records managers and archivists, information technology staff, legal staff, and the various business units in an organization. These people bring together the knowledge and skills required to propose institutional priorities and advocate for resources, write requirements for systems, undertake the acquisition and implementation of systems, and carry out training, compliance, data management, and long-term digital preservation.

Records managers and archivists usually control the retention policy and records classification scheme. They also understand the organization's business processes, the nature of the records created by those processes, and the metadata required to support management and access. Records managers routinely train staff in good recordkeeping and are the best equipped to monitor compliance with policies. Archivists know at the time of creation which records are likely to require long-term preservation, and they are knowledgeable about the systems, policies, processes, and results that are required for a viable digital preservation program.

Information technology staff usually controls the system architecture, software acquisition and implementation, data storage, and disaster recovery for systems. They have the knowledge to articulate system requirements in a manner that is understood by vendors and to ensure that software applications have the ability to interact and run in the corporate technology environment. Legal staff provides system requirements for managing legal discovery and for producing electronic records that will stand up in court.

Most important, however, are the business units and end users. Ultimately, if the systems and processes designed for managing electronic records are difficult to use or fail to do what the business unit requires, then they will not be used.

CONCLUSION

Institutional archivists and records managers are evolving into proactive leaders as they bring their knowledge and skills to the task of preserving and integrating access to their organization's knowledge, information, and records. In so doing, they are making adjustments to some of the traditional practices of their professions and adopting a flexible approach to collaboration, all of which require a certain amount of risk-taking. Institutional archives and records management programs are working together to

analyze the institutional context, functions, and business processes that inform the creation of records and then using this information to make informed appraisal and access decisions. Working together, archivists and records managers understand better the uses and values that characterize institutional records and then combine their skill sets to communicate requirements for records creation and management of records over their entire life cycle.

In managing institutional archives repositories, archivists adapt traditional methodologies of arrangement and description to suit the nature of the records in their repository, and they negotiate an access policy that balances open access to records with the business needs of the institution.

At the same time, institutional archivists and records managers must be knowledgeable of standards and best practices for managing electronic records and be proactive in planning and implementing institution-wide systems for managing e-mail, data in enterprise applications, and records created by desktop applications. To this process they bring knowledge of records and business processes, records creation and retention policies, training requirements, and compliance monitoring. They also bring a strong liaison with the creators of records across the institution. Archivists and records managers have an especially important role to play in communicating requirements for digital preservation programs.

The future promises to bring more challenges to institutional archivists and records managers as institutional electronic records are created, transmitted, and retained in many and varied communication devices and stored in data repositories no longer managed by the institution. In addition, many futurists are predicting a greater socialization of information in the coming years, stimulated in part by Web 2.0 technologies. These trends will challenge the ability of archivists and records managers to manage records and will test an institution's real and perceived need for control over its records and information.

ACKNOWLEDGMENTS

Intellectual Freedom and the American Library Association (ALA): Historical Overview *[ELIS Classic]*

Judith F. Krug

Office for Intellectual Freedom, American Library Association, Chicago, Illinois, U.S.A.

Abstract

One of the major initiatives of the American Library Association has been to promote intellectual freedom in society. The author of this entry was one of the driving forces of this effort over many years. Though, as Krug noted, intellectual freedom has been understood in many different ways, a simplified definition can be taken as the right to freedom of thought, expression, and access to informational materials of any kind. In this entry, Krug described the long, rich history of librarians' efforts to oppose censorship and assure intellectual freedom for library users.

—*ELIS Classic*, from 2003

INTRODUCTION

At the outset, two myths can be dispelled: 1) intellectual freedom in libraries is a tradition; and 2) intellectual freedom has always been a major, if not the major, part of the foundation of library service in the United States. Both myths, assumed by many librarians, are grounded in the belief that librarians support a static concept of intellectual freedom. Nothing, however, could be farther from the truth.

The attitude of librarians toward intellectual freedom has undergone continual change since the late 1800s when, through the American Library Association (ALA), the profession first began to approach such issues with the semblance of a unified voice. The ALA, however, has never endorsed a uniform definition of "intellectual freedom." Instead, through the council, ALA's governing body, the Intellectual Freedom Committee (IFC), and the Office for Intellectual Freedom (OIF), ALA has promoted a variety of principles aimed at fostering a favorable climate for intellectual freedom but without the limits imposed by a rigid definition. This approach has permitted a broad definition capable of meeting the needs of librarians as they arise.

CENSORSHIP OF PUBLISHED MATERIALS

The catalyst spurring librarians to take initial steps toward supporting intellectual freedom was the censorship of specific publications. "Censorship" in this context means not only deletion or excision of parts of published materials but also efforts to ban, prohibit, suppress, proscribe, remove, label, or restrict materials. Opposition to these activities emanated from the belief that freedom of the mind is basic to the functioning and maintenance of

democracy as practiced in the United States. Such democracy assumes that educated, free individuals possess powers of discrimination and are to be trusted to determine their own actions. It assumes further that the best guarantee of effective and continuing self-government is a thoroughly informed electorate capable of making real choices. Denying the opportunity of choice, for fear it may be used unwisely, destroys freedom itself. Opposition to censorship derives naturally from the library's historic role as an educational institution providing materials that develop individuals' abilities, interests, and knowledge. Censorship denies the opportunity to choose from all possible alternatives, thereby violating intellectual freedom. The library profession has aimed to ensure every individual's freedom of the mind so that society as a whole benefits. Even in this central area, however, the professional position has fluctuated, being influenced by such factors as taste, quality, responsibility, morality, legality, and purpose.

One early incident concerning censorship, involving a substantial number of librarians, occurred in 1924 when the Librarians' Union of the American Federation of Labor reported that Carnegie Libraries fostered "a system under which only books approved in a certain manner may be placed on Carnegie Library shelves and that amounts to censorship and is so intended."^[1] The ALA Executive Board considered the union's charges and offered to enlist volunteers to investigate the claims. Apparently, however, the union did not act on the offer, and the matter was not considered further by the executive board.

In 1934, the association recorded its first protest against the banning of a specific publication, *You and Machines*, a pamphlet by William Ogburn. Prepared for use in Civilian Conservation Corps camps under a grant from the American Council on Education, the pamphlet was denied circulation by the camps' director, who believed it would

induce a philosophy of despair and a desire to destroy existing economic and political structures. Initially, the ALA president and executive secretary wrote a joint letter to President Franklin D. Roosevelt, stating that “[governmental] censorship on a publication of this character written by a man of recognized authority is unthinkable.”^[2] Later the board discussed the banning further and appointed a committee to draft another letter for approval by the ALA Council. The result was a formal request that President Roosevelt “make it possible for the U.S. Commissioner of Education and the Education Director of the Civilian Conservation Corps to direct the educational policies to be operative in these camps and to make available the reading matter essential in a modern program of education.”^[2]

These examples illustrate the association’s wavering position and reflect the ambivalent attitude of the profession as a whole regarding censorship. A review of library literature reveals relatively few articles on intellectual freedom prior to the 1930s, and many of the articles that did appear supported censorship and only quibbled over the degree and nature of it. Typical was the opinion of ALA President Arthur E. Bostwick, whose inaugural address at the 1908 Annual Conference included these remarks:

‘Some are born great; some achieve greatness; some have greatness thrust upon them.’ It is in this way that the librarian has become a censor of literature. . . Books that distinctly commend what is wrong, that teach how to sin and how pleasant sin is, sometimes with and sometimes without the added sauce of impropriety, are increasingly popular, tempting the author to imitate them, the publishers to produce, the bookseller to exploit. Thank Heaven they do not tempt the librarian.^[3]

Given the multiplicity of professional attitudes toward censorship of print materials, it is not surprising that censorship of nonprint media was once viewed as completely outside the concerns of the profession. For example, as late as 1938, the ALA Executive Board believed it was inappropriate to protest when the Federal Communications Commission forced a radio station to defend its broadcast of Eugene O’Neill’s *Beyond the Horizon*.^[4]

The association’s basic position in opposition to censorship finally emerged in the late 1930s, when John Steinbeck’s *The Grapes of Wrath* became the target of censorship pressures around the country. It was banned from libraries in East St. Louis, Illinois; Camden, New Jersey; Bakersfield, California; and other localities. Although some objected to the “immorality” of the work, most opposed the social views advanced by the author.

The initial response of the ALA to the pressures against *The Grapes of Wrath* was the adoption in 1939 of the *Library’s Bill of Rights*, the precursor of the present *Library Bill of Rights*, the profession’s basic policy statement on intellectual freedom involving library materials.

In 1940, 1 year after adoption of the *Library’s Bill of Rights*, the association established the Intellectual Freedom Committee (IFC). (Originally called the Committee on Intellectual Freedom to Safeguard the Rights of Library Users to Freedom of Inquiry, the Committee’s name was shortened by council action in 1948 to Committee on Intellectual Freedom and inverted through usage to Intellectual Freedom Committee.) The 1940 charge to the IFC was “to recommend such steps as may be necessary to safeguard the rights of library users in accordance with the Bill of Rights and the *Library’s Bill of Rights*, as adopted by Council.”^[5] Although the IFC’s role has varied, its main function has been to recommend policies concerning intellectual freedom, especially—but not limited to—matters involving violations of the *Library Bill of Rights*. Although its original statement of authority referred only to library users, in reality the IFC became active in promoting intellectual freedom for librarians and patrons as well. Its diversified role was recognized and formalized in 1970 when the council approved a revised statement of authority:

To recommend such steps as may be necessary to safeguard the rights of library users, libraries, and librarians, in accordance with the First Amendment to the United States Constitution and the *Library Bill of Rights* as adopted by the ALA Council. To work closely with the Office for Intellectual Freedom and with other units and officers of the Association in matters touching intellectual freedom and censorship.^[6]

The original *Library’s Bill of Rights* focused on unbiased book selection, a balanced collection, and open meeting rooms. It did not mention censorship or removal of materials at the behest of groups or individuals. Over the years, however, the document has been revised, amended, and interpreted, often in response to specific situations with general implications. The first change, a 1944 amendment against banning materials considered “factually correct,” was occasioned by attacks on *Under Cover*, an expose of Nazi organizations in the United States, and *Strange Fruit*, a novel about interracial love. Reference to “factually correct” was later dropped, but the directive against removal of materials remained. Opposition to censorship of nonprint media was amended to the document in 1951 because of attacks on films alleged to promote communism. To combat suppression of communist materials or other allegedly “subversive” publications, the association issued its “Statement on Labeling,” which stated that designating materials “subversive” is subtle censorship, because such a label predisposes readers against the materials. Responding to pressures against materials about civil rights activities, a 1967 amendment to the *Library Bill of Rights* warned against excluding materials because of the social views of the authors. In its 1971 “Resolution on Challenged Materials,” the

association counseled libraries not to remove challenged materials unless, after an adversary hearing in a court of law, the materials were judged to be outside the protection of the First Amendment.

Changing circumstances necessitate constant review of the *Library Bill of Rights* and often result in position statements, called *Interpretations*, to clarify the document's application. The most recent *Interpretations* are Access to Electronic Information, Services and Networks adopted by the ALA Council in January 1996 and Intellectual Freedom Principles for Academic Libraries, approved by the ACRL Board in June 1999 and adopted by the ALA Council in July 2000.

Taken together, these documents recognize and explain that censorship of any materials, in any guise, eventually affects the library. The *Library Bill of Rights*, therefore, provides principles on which libraries may stand to oppose censorship and promote intellectual freedom. Referring directly to censorship practices, the *Library Bill of Rights* states that no library materials should be "excluded because of the origin, background, or views of those contributing to their creation" and that materials should not be "proscribed or removed because of partisan or doctrinal disapproval."

On its face, the profession's view of intellectual freedom is a pure one, based on a strict reading of the First Amendment to the U.S. Constitution, which states, "Congress shall make no law . . . abridging freedom of speech, or of the press." Within the limits defined by the United States Supreme Court (e.g., the legal doctrines governing obscenity, defamation, or "fighting words"), the position relies on the extension of First Amendment principles via the Fourteenth Amendment to the states and their agencies, including publicly supported libraries. (Some state constitutions actually provide greater protection for free speech than does the First Amendment as interpreted by the United States Supreme Court, but no state is permitted to provide less protection for these fundamental rights.) In actual practice, the purist position sometimes gives way to compromises by individual librarians, resulting in removal, labeling, or covert nonselection of certain materials.

If followed by librarians and governing bodies, however, the association's policy statements provide an effective means of helping to prevent library censorship. Ideally, application of these policies to materials selection, circulation practices, and complaint handling establishes the library as an indispensable information source for individuals exercising their freedom of inquiry.

FREE ACCESS TO LIBRARY MATERIALS

Access to library collections, and services is another concern of the profession. For intellectual freedom to flourish, opposition to censorship of materials is not

enough. Free access to materials for every member of the community also must be ensured. The ALA first recognized this in the 1939 *Library's Bill of Rights*, which included a proviso that library meeting rooms be available on equal terms to all groups in the community regardless of the beliefs and affiliations of their members.

Another policy on free access emerged from a study of segregation made by the association's Special Committee on Civil Liberties during the late 1950s. One result of the study was a 1961 amendment to the *Library Bill of Rights*, stating that "the rights of an individual to the use of a library should not be denied or abridged because of his race, religion, national origins, or political views." This amendment was broadened in 1967, when "social views" and "age" were incorporated to emphasize other areas of potential discrimination. "Age" was included to resolve a long-standing debate on the right of minors to have access to libraries on the same basis as adults.

In 1971, at the urging of the Task Force on Gay Liberation of the Social Responsibilities Round Table, the association recommended that libraries and ALA members strenuously combat discrimination in serving any individual from a minority, whether it be an ethnic, a sexual, a religious, or any other kind of minority. In 1980, the *Library Bill of Rights* was revised to encompass all discrimination based on "origin, age, background, or views." Interpretations of the *Library Bill of Rights* addressing specific issues that fall under these deliberately broad categories include "Access for Children and Young People to Videotapes and Other Nonprint Formats," "Access to Resources and Services in the School Library Media Program," "Free Access to Libraries for Minors," "Economic Barriers to Information Access," and "Access to Library Resources and Services Regardless of Gender or Sexual Orientation."

Another aspect of the library patron's access to materials was broached in 1970 when the Internal Revenue Service requested permission from several libraries to examine circulation records to determine the names of persons reading materials about explosives and guerilla warfare. The association responded by developing its "Policy on Confidentiality of Library Records," urging libraries to designate such records as confidential and accessible only "pursuant to such process, order, or subpoena as may be authorized under the authority of, and pursuant to, federal, state, or local law relating to civil, criminal, or administrative discovery procedures or legislative investigatory power." The rationale of the policy was that circulation records are purely circumstantial evidence that a patron has taken a book out of the library and that fear of persecution or prosecution may restrain users from borrowing any conceivably controversial materials, for whatever purpose.

The question of library records and the confidentiality of relationships between librarians and library users arose again in 1971 regarding the "use of grand jury procedure

to intimidate anti-Vietnam War activists and people seeking justice for minority communities.” In response, the association asserted “the confidentiality of the professional relationships of librarians to the people they serve, that these relationships be respected in the same manner as medical doctors to their patients, lawyers to their clients, priests to the people they serve,” and that “no librarian would lend himself to a role as informant, whether of voluntarily revealing circulation records or identifying patrons and their reading habits.”

In late 1987, it was disclosed that FBI agents were visiting libraries in what are best described as “fishing expeditions.” Agents generally first approached library clerks and solicited information on the use of various library services (e.g., interlibrary loan, database searches) by “suspicious looking foreigners” and, in some instances, asked to see the library’s circulation records.

A public confrontation between the IFC and the FBI eventually ensued. The IFC stressed the inextricability of First Amendment and privacy rights, as well as the fact that the bureau was requesting that librarians violate not only a professional ethic but also the law in 38 states and the District of Columbia. (As of this writing, there are confidentiality laws in 48 states and the District of Columbia and an attorney general’s opinion supporting confidentiality in two states.) The bureau refused to back away from what it characterized as a program to alert librarians to the possibility that libraries were being used by foreign agents as a place to recruit operatives, that librarians themselves were sometimes targeted for approach by foreign agents, and that valuable material was being stolen by these agents and their operatives. The IFC emphasized, in congressional testimony and in the media, the principle of open access to publicly available information and the central role of libraries in this society as providers of that access.

In the fall of 1989, through a Freedom of Information Act (FOIA) request, the ALA obtained documents from the FBI in which 266 individuals, all of whom had in some way criticized the Library Awareness Program (LAP), were identified as subjects of FBI “index checks.” These documents also suggested that the Library Awareness Program covered parts of the country other than solely New York City, as previously claimed by the FBI.

Early in 1990, the ALA wrote to President George Bush, then director of the FBI William Sessions, and the relevant House and Senate committees, urging that the LAP be discontinued and that the files of the 266 individuals be released to them and expunged from FBI records. Director Sessions responded in March 1990 by defending the program and denying that any investigation of the 266 had taken place, claiming that “index checks” were administrative and not investigative in nature. Subsequently, individuals were urged to make their own FOIA requests, but only one person who filed such a request later reported receiving any information from the FBI.

In addition, the ALA filed yet another FOIA request, which was denied, as was the appeal of that denial, on the grounds that the FBI was in litigation with the National Security Archive (NSA) over the same issue. The FBI promised to give the ALA any information released to the NSA and eventually did so. Nevertheless, the ALA reserved the right to bring suit against the FBI for denying its right of appeal and obstructing a legitimate attempt to gain information under the Freedom of Information Act.

The FBI has never publicly abandoned the Library Awareness Program and may still be conducting it.

Federal agencies are not alone in attempting to make use of library patron records. Local law enforcement officials, journalists, students, parents, fund-raisers, marketing professionals, civil litigants, and politicians have been known to seek borrowing records, registration data, mailing lists, and other information about library patrons. In 1990, a library director in Decatur, Texas, challenged one such attempt in court and won an important victory for library confidentiality policies. In *Decatur Public Library v. The District Attorney’s Office of Wise County*,¹⁷¹ the district attorney, investigating a child abandonment case, subpoenaed the records of all libraries in Wise County, requesting the names, addresses, and telephone numbers of all individuals who had checked out books on childbirth within the previous 9 months, the titles they borrowed, and the dates the materials were checked out and returned. The police had no evidence indicating that the person who abandoned the child might have borrowed library books or otherwise used the library. They were simply conducting a “fishing expedition.”

The director of the Decatur Public Library refused to comply with the subpoena and, with the help of the city attorney, filed a motion to quash it on behalf of the library’s patrons. On May 9, 1990, Judge John R. Lindsey ruled in favor of the library and quashed the subpoena. His decision recognized the library’s standing to assert a constitutional privilege on behalf of its unnamed patrons and clients, affirmed a constitutional right of privacy available to patrons, and held that the state was unable to demonstrate a compelling governmental objective under its police powers or other legitimate function of government to warrant intrusion of those rights.

In 1995, the issue of library user confidentiality again reached the courts in connection with a lawsuit brought by a tobacco company, Brown and Williamson, against the University of California. The company alleged that the University of California at San Francisco library possessed in its collection documents stolen from the company that purportedly showed that the tobacco industry had known of a link between smoking and cancer for many years and had failed to disclose it. The documents had previously been leaked to the press and discussed in congressional hearings at the time the lawsuit was filed. The lawsuit sought not only return of the documents but a list of all library patrons who had access to them and a

description of the nature of those users' research and publications.

The ALA's sister organization, the Freedom to Read Foundation, identified the case as one of extreme importance, with potential to set positive precedent in favor of First Amendment protection for library-user privacy, and filed an amicus brief explaining the crucial link between library confidentiality and First Amendment rights. Although the case ultimately was resolved without reaching the confidentiality issue, the fact that a request for library-user records was made as part of the lawsuit indicates the breadth of circumstances in which a threat to confidentiality may arise.

Through the association's various position statements, the profession has established a code of free access to services and materials for all library users. Opposed to using the library as a means of intimidating patrons, the profession strives to enhance the intellectual freedom of the library user by providing not only all materials requested but also free and equal access to all materials without fear of recrimination for pursuing one's interests.

THE LIBRARIAN AND INTELLECTUAL FREEDOM

Although the profession, through ALA, formulates policies to help ensure a climate favorable to intellectual freedom, the individual librarian is the key to achieving the end result. Adherence to the *Library Bill of Rights* by individual librarians is the only means of effecting the profession's goals. Consequently, the concept of intellectual freedom also considers the individual librarian's intellectual freedom, both in pursuit of professional responsibilities and in personal life. Several agencies within, or closely affiliated with, ALA encourage and protect the librarian's commitment to the principles of intellectual freedom. In relation to support for intellectual freedom, the *Code of Ethics* of the American Library Association, adopted by the ALA Council in June 1995, specifically states: "We uphold the principles of intellectual freedom and resist all efforts to censor library materials."

From 1940 until 1967, most of such activities were centered in the Intellectual Freedom Committee. For many years, the IFC not only recommended policies but also directed a variety of educational efforts, including collecting and publicizing information about censorship incidents, sponsoring censorship exhibits at conferences, conducting preconferences on intellectual freedom themes, and planning complementary programs to further the association's goals regarding intellectual freedom.

One of these complementary programs is the Office for Intellectual Freedom (OIF), established in December 1967. OIF evolved from a 1965 preconference on intellectual freedom held in Washington, DC. That meeting recommended establishing an ALA headquarters unit to conduct and coordinate the association's intellectual

freedom activities and to provide continuity for the total program. The goal of OIF is to educate librarians and the general public on the importance of intellectual freedom, relieving the IFC of this task and allowing it to concentrate on developing policy. The OIF serves as the administrative arm of the Intellectual Freedom Committee and bears the responsibility for implementing ALA policies on intellectual freedom, as approved by the ALA Council. The philosophy of the Office for Intellectual Freedom is based on the premise that if librarians are to appreciate the importance of intellectual freedom, they must first understand the concept as it relates to the individual, the institution, and the functioning of society. Believing that with understanding comes the ability to teach others, OIF maintains a broad program of informational publications, projects, and services.

The regular OIF publication is the bimonthly *Newsletter on Intellectual Freedom*. The Office also prepares special educational materials, (e.g., the *Banned Books Week Resource Kit* and others as need dictates). In addition, OIF works closely with ALA Publishing to develop relevant monographs. Recent titles have included *The Intellectual Freedom Manual, Sixth Edition*, by the Office for Intellectual Freedom (ALA, 2001); *Libraries, Access, and Intellectual Freedom: Developing Policies for Public and Academic Libraries*, by Barbara M. Jones (ALA, 1999); *Libraries, the First Amendment, and Cyberspace: What You Need to Know*, by Robert S. Peck (ALA, 2000); and *Speaking Out! Voices in Celebration of Intellectual Freedom* by Ann K. Symons and Sally Gardener Reed (ALA, 1999). OIF also distributes documents, articles, brochures, and all ALA policy statements concerning intellectual freedom in print and on the Web. As part of its information program, OIF maintains and distributes a banned books exhibit. The exhibit is available for display at national, state, and local conferences, workshops, seminars, and other meetings.

The Office for Intellectual Freedom advises and consults with librarians confronting potential or actual censorship problems. Telephone and letter requests about materials that have drawn the censorial efforts of an individual or group in the community prompt efforts to give appropriate assistance. Another means of assistance established in 1994 is the Intellectual Freedom Action Network, a group of concerned volunteers who have identified themselves as willing to stand up in support of intellectual freedom when controversy comes to their area and to alert OIF to the activities of censorship pressure groups in their communities. The OIF coordinates the Action Network, calling on its members when necessary to write letters, attend meetings, or provide moral support to librarians fighting censorship in their localities.

OIF also coordinates the Intellectual Freedom Committee's relations with other organizations having similar concerns. These include the intellectual freedom committees of the ALA divisions and state library association intellectual freedom committees. Close contact with

nonlibrary organizations, such as the Association of American Publishers, the American Booksellers Foundation for Free Expression, the American Civil Liberties Union, the National Coalition against Censorship, and others, is also maintained.

As ALA's intellectual freedom program developed, the need for an organizational forum through which individual ALA members could participate in intellectual freedom activities according to their varying levels of interest began to be felt. At the 1973 Annual Conference in Las Vegas, the Intellectual Freedom Round Table (IFRT) was organized as the Association's membership, activity program for intellectual freedom. The activities of the round table supplement OIF's education program and offer opportunities for ALA members to become active in the association's intellectual freedom efforts.

The IFRT sponsors three intellectual freedom awards. The annual State and Regional Achievement Award, given by the IFRT since 1984, was revised in 1991. Formerly presented to a state Intellectual Freedom Committee, the award has been expanded to include "state educational media association intellectual freedom committee[s], state intellectual freedom coalition[s], legal defense fund[s] or other such group that has implemented the most successful and creative state intellectual freedom project during the calendar year. The award also may be presented for on-going or multiyear projects." In 1975, IFRT established the John Philip Immroth Memorial Award for Intellectual Freedom, given annually in memory of the cofounder and first chairperson of the round table, "to honor notable contributions to intellectual freedom and demonstrations of personal courage in defense of freedom of expression." Biennially, the IFRT sponsors the Eli M. Oboler Award, presented for the best published work in the area of intellectual freedom.

The Intellectual Freedom Committee, the Office for Intellectual Freedom, and the Intellectual Freedom Round Table are the primary agencies for establishing and promoting the association's positions on questions involving intellectual freedom. In addition, the Intellectual Freedom Action Network supports these positions and responds to controversies on the local level. The element in the association's program in support and defense of intellectual freedom that takes the most aggressive, proactive role, however, is the Freedom to Read Foundation.

Incorporated in November 1969, the Freedom to Read Foundation was ALA's response to librarians who increasingly wanted defense machinery to protect their jobs from jeopardy when they undertook to challenge violations of intellectual freedom. Another primary objective in establishing the foundation was to have a means through which librarians and other concerned individuals and groups could begin to set legal precedents for the freedom to read. The foundation was created outside the structure of ALA and, to ensure its full freedom to act with vigor in

the legal arena, it remains legally and financially independent. But the foundation is closely affiliated with ALA through the ex officio membership of ALA officers on its board of trustees, and through its executive director, who also serves as director of the ALA Office for Intellectual Freedom.

A program of education on the importance of, and the necessity for a commitment to, the principles of intellectual freedom requires assurance that such commitment will not result in reprisals, such as legal prosecution, financial loss, or personal damage. The Freedom to Read Foundation attempts to provide that assurance through financial and legal assistance and legal challenges to restrictive legislation, thereby helping to create a favorable climate for intellectual freedom. Through the provision of financial and legal assistance, the foundation attempts to negate the necessity for librarians to make the difficult choice between practical expediency (i.e., keeping a job) and upholding principles, such as in selecting materials for library collections. Through its various projects and grants, the foundation hopes to establish those principles enunciated in the *Library Bill of Rights* as legal precedents rather than mere paper policies.

Established by the Freedom to Read Foundation, but now formally independent, the LeRoy C. Merritt Humanitarian Fund was created in 1970. The Merritt Fund was established by the foundation's board of trustees in recognition of individuals' need for subsistence and other support when their positions are jeopardized or lost as a result of defending intellectual freedom. This special fund offers short-term, immediate assistance even prior to the development of all pertinent facts in a particular case, whether or not legal action has been taken.

In the combined forces of the Intellectual Freedom Committee, the Office for Intellectual Freedom, the Intellectual Freedom Round Table, the Intellectual Freedom Action Network, and the Freedom to Read Foundation, along with the LeRoy C. Merritt Humanitarian Fund, the library profession has available a complete program to support the practice of intellectual freedom. The profession, however, has not yet achieved the same success in a closely related area, that of the librarian's personal rather than professional intellectual freedom. The question of what support should be given to librarians who suffer professionally because of personal beliefs and actions has been approached in individual cases but has not been fully resolved.

One of the first instances involving potential recriminations in a professional capacity as a result of personal beliefs occurred in the late 1940s, with the advent of "loyalty oaths" and "loyalty programs" designed to ferret out communists and "subversives." The Intellectual Freedom Committee faced the loyalty issue with its Policy on Loyalty Programs, first adopted by the council in 1948 and revised in 1951. When another case arose in Florida in 1969, the Policy on Loyalty Programs was reexamined

and again revised. The last revision, adopted by the council in January 1971, states in part the following:

The American Library Association strongly protests loyalty programs which inquire into a library employee's thoughts, reading matter, associates, or membership in organizations, unless a particular person's definite actions warrant such investigation. We condemn loyalty oaths as a condition of employment and investigations which permit the discharge of an individual without a fair hearing.^[8]

In 1969, another incident arose involving a librarian who lost his position because of actions, based on personal beliefs, taken in his capacity as a private citizen. T. Ellis Hodgin was fired as city librarian of Martinsville, Virginia, shortly after he joined a lawsuit challenging the constitutionality of a religious education course taught in the city school his daughter attended. He also had been active in civil rights efforts. Hodgin's situation sparked a controversy among librarians, resulting in a recommendation from the Intellectual Freedom Subcommittee of the Activities Committee on New Directions for ALA (ACONDA):

The scope of intellectual freedom encompasses considerably more than just the freedom to read. Support must also be rendered to the librarian who is fired for sporting a beard, for engaging in civil rights activities, etc., etc. And he should not have to claim "poverty" in order to receive it.^[9]

The recommendation, however, was not approved as part of the final ACONDA report.

Some concerned librarians responded to Hodgin's plight by organizing the National Freedom Fund for Librarians (NFFL), which collected several thousand dollars to aid him. (When the NFFL disbanded in 1971, its cash balance was sent to the LeRoy C. Merritt Humanitarian Fund.)

Hodgin also appealed to the Freedom to Read Foundation for assistance to defray the financial hardship he suffered when he lost his position. In June 1970, the foundation's executive committee awarded him \$500

for having suffered in his defense of freedom of speech as a result of which he lost his position as a librarian. Inasmuch as it is the obligation of the librarian to protect free speech and a free press through his work as a librarian, it is then particularly appropriate that, when he is deprived of his job because of his own exercise of free speech, the Freedom to Read Foundation assist him in the defense of his freedom.^[10]

A second grant of \$500 was made to Hodgin in January 1971 for the specific purpose of perfecting an appeal of his suit for reinstatement to the U.S. Supreme Court.

The limits of intellectual freedom were again debated by the profession when the case of J. Michael McConnell arose in 1970. The Intellectual Freedom Committee found that McConnell's rights "under the First Amendment have been violated" because he met reprisals for freely expressing his sexual preference.^[11] On that basis, the LeRoy C. Merritt Humanitarian Fund granted \$500 to help defray financial hardship occasioned by his inability to find another job.

The question of how far librarians are willing to extend the scope of intellectual freedom for the benefit of their colleagues was raised anew in 1979 by the case of Utah librarian Jeanne Layton. In September 1979, Layton was dismissed from her position as library director in Davis County after she refused to comply with requests to remove the novel *Americanas*, by Don DeLillo, from library shelves. The following month she filed suit to regain her job.

The suit was supported from the beginning by the Freedom to Read Foundation, but it soon became clear that the legal battle would be a lengthy and very costly one. Both the Intellectual Freedom Committee and the Freedom to Read Foundation designated the case a priority for 1980. The Utah Library Association rallied librarians and others statewide in support. At the 1980 ALA Annual Conference in New York, the Freedom to Read Foundation announced that it would match two dollars for every dollar contributed to Jeanne Layton's defense from June 27, 1980, to December 31, 1980, up to a limit of \$10,000 in matching funds. The response was, in the words of Foundation President Florence McMullin, "nothing short of overwhelming." When the challenge expired, \$6024 had been received, of which \$5000 was matched "two for one" by the foundation. Moreover, Jeanne Layton won her suit and regained her job, and one of her main antagonists was defeated for reelection to the county commission.

Although the question of how far librarians will go to support colleagues in defense of intellectual freedom will always be resolvable only on a case-by-case and issue-by-issue basis, the response to Layton's courageous stand surely indicates that in general the library profession takes its responsibilities on this front seriously indeed.

THE LIBRARY AND INTELLECTUAL FREEDOM

Each aspect of intellectual freedom in libraries that has been discussed to this point has involved library users and their access to all published materials, as well as librarians and their practice of professional or personal intellectual freedom.

One aspect of intellectual freedom remains to be examined: the library as an institution and the nature of its role in social change and education. Continually debated within the profession and the American Library

Association, the issue has been summarized as “neutrality versus advocacy.” In essence, the question is, can libraries, as institutions, advocate social or political causes and still maintain their image as providers of views representing all sides of all questions?

Whenever the question is raised, it initiates further queries. For example, what constitutes advocating a cause—biased book selection, biased displays, prejudicial assignment of library meeting rooms? Or, what constitutes a cause—peace, ecology, democracy? If a library sponsors a display of books on peace, to maintain neutrality must it also sponsor a display on war? The questions are complex, and the answers have shown no uniformity whatsoever. The American Library Association itself has vacillated on the main issue, reaching only a partial resolution in the late 1960s and the early 1970s.

At the 1969 Annual Conference in Atlantic City, the membership and the council debated whether the association should take a public stand opposing the war in Vietnam or opposing deployment of an antiballistic missile system (ABM). It was argued that because political and moral issues are so deeply entangled with education and library issues, institutions such as ALA and libraries are obligated to take such positions. Those who opposed such positions argued in favor of neutrality on questions not directly related to libraries. They argued that intellectual freedom for those librarians opposed to the majority view would be violated if the association attempted to take stands on social and political issues. They further maintained that they had tradition on their side, because the association had always declined to take a stand on issues not directly related to libraries. That argument, of course, was incorrect. The association had previously taken stands in some instances and refused to do so in others.

In June 1921, for example, the ALA Council espoused a very decided position on the question of disarmament after the First World War. In a strong resolution, the council stated the following:

WHEREAS, The members of the American Library Association had full demonstration of the pain and pinch that belongs to war and the increased cost of all necessities, both personal and professional, caused thereby; and

WHEREAS, The exigencies of international conditions brought about by the cost of war is appalling from every standpoint; and

WHEREAS, We believe the example of the United States in this matter will be followed by the other nations;

THEREFORE BE IT RESOLVED, That the American Library Association urge upon the president of the United States and Congress the initiative of a movement leading to a reduction of armament at the earliest possible moment; and be it further

RESOLVED, That a request be made by the members of the American Library Association to their individual congressman for such action and that a record be made of the replies.^[12]

However, in 1928, when faced by a request from the American Civil Liberties Union that ALA adopt “one or more resolutions on civil liberty,” the ALA Executive Board declined, saying the association “does not take actions on questions outside the library and bibliographic field.”^[13] That was similar to the philosophy that prevailed in 1969, when the Vietnam and ABM resolutions failed to pass the council. The question arose again, however, at the 1970 and 1971 Midwinter Meetings and Annual Conferences. After a great deal of debate, the Council voted at its 1970 Annual Conference in Detroit to “define the broad social responsibilities of ALA in terms of the willingness of ALA to take a position on current critical issues with the relationship to libraries and library service clearly set forth in the position statements.”^[14]

In line with this policy, a carefully reworded resolution opposing the war in Vietnam was adopted by the council 1 year later:

WHEREAS, The stated objective of the American Library Association is the promotion and improvement of library service and librarianship; and

WHEREAS, Continued and improved library service to the American public requires sustained support from the public monies; and

WHEREAS, The continuing U.S. involvement in the conflict in Southeast Asia has so distorted our national priorities as to reduce substantially the funds appropriated for educational purposes, including support for library services to the American people; and

WHEREAS, Continued commitment of U.S. arms, troops, and other military support has not contributed to the solution of this conflict;

BE IT THEREFORE RESOLVED, That the American Library Association calls upon the president of the United States to take immediately those steps necessary to terminate all U.S. military involvement in the present conflict in Southeast Asia by December 31, 1971, and to insure the reallocation of national resources to meet pressing domestic needs.^[15]

With approval of the Vietnam resolution, the association seemed to give broader interpretation to the old “library and bibliographic field.” However, this more permissive interpretation still did not resolve the more basic question of whether libraries themselves should follow the course of neutrality or advocacy.

The contradiction was further focused in July 1974, when ALA endorsed the Equal Rights Amendment.

ALA's support for ERA went much farther than its opposition to U.S. military involvement in Southeast Asia. In 1977, the council voted not to hold conferences in states that had not ratified the amendment. In June 1978, the council endorsed the ERA Extension Resolution and, at the 1979 Midwinter Meeting, established an ERA task force charged with assisting and consulting with "ALA Chapters in carrying out the commitment to passage of the Equal Rights Amendment in ways best suited to the individual states."^[16]

The association justified this active support of the proposed amendment, first, by noting the support already expressed by other professional associations "by reason of its beneficial implications for all persons in the American society," and, more specifically, as an outgrowth of ALA's policy requiring equal employment opportunity in libraries, adopted at the 1974 Midwinter Meeting. The resolution in support of ERA noted that "women constitute 82 percent of the library profession." Hence, it was argued, "equal employment required support of equal rights for women."^[17] None of the operative resolutions on ERA addressed themselves to the content of library collections. Opponents of the amendment and pro-ERA advocates of ALA neutrality, however, were quick to argue that library users "have a right to expect the library to furnish them with uncensored information on both sides of this and all other issues. Adoption of advocacy positions and participation in boycotts cannot help but strike a blow at the public's confidence in the fair-mindedness and even-handedness of librarians."^[18]

Yet another aspect of the advocacy versus neutrality conundrum was addressed by the association in 1987 at its annual conference in San Francisco. David Henington, director of Houston Public Library, brought to the IFC for its response and assistance an antiapartheid ordinance passed and implemented by the City of Houston. This ordinance required that all city agencies obtain certification from suppliers of goods and services that they had no affiliates in, and did no business with, the Republic of South Africa. The Houston City Council subsequently voted to exempt both the public library and the city zoo from the requirements of the ordinance. Henington asserted that this requirement was causing serious acquisition problems for the library. Major information services, such as the New York Times Company, the *Wall Street Journal*, and leading publishers, refused to sign such certificates. Some refused because they have reporters in South Africa, one religious group because it has missionaries there, and on principle, in the belief that the free flow of information both into and out of the Republic of South Africa must be defended and enlarged for the sake of those struggling to dismantle the apartheid system there. Because it did not have a copy of the ordinance in hand and because it had received reports of similar ordinances elsewhere, the IFC voted to explore the matter further.

Two ALA members decided that the issue should be taken to the membership at that conference, and they presented a resolution at the membership meeting. The resolution stressed the intellectual freedom implications of this policy and asked that ideas and information be exempted from the laudable goal of enforcing economic sanctions against the Republic of South Africa for its abhorrent apartheid system. A heated encounter ensued between the presenters and other supporters of the resolution and those who saw it as supportive of apartheid and, therefore, racist. The resolution was resoundingly defeated.

At the 1988 Annual Conference in New Orleans, the membership adopted a resolution reaffirming its commitment to Article 19 of the Universal Declaration of Human Rights: "Everyone has the right to freedom of opinion and expression; this right includes freedom to hold opinions without interference and to seek, receive and impart information and ideas through any media regardless of frontiers."

Measuring the Profession's Response

At the present time, the profession uniformly disdains censorship of published materials, print or nonprint. The attitude toward user access is somewhat uniform but contains a great deal of dissent on the question of access for minors to all the materials in a library collection. On the question of the librarian's professional practice of intellectual freedom, there is near agreement that every effort should be made to encourage and protect this aspect of librarianship. The librarian's personal intellectual freedom, on and off the job, presents some points of agreement, but major areas of dissent still exist. The same is true in the area of institutional neutrality versus advocacy.

One conclusion from a review of the history, status, and future of intellectual freedom in libraries is that the American Library Association's positions and programs provide one of the few gauges for measuring the profession's response to the problems of defining, promoting, and defending the concept. The evolving position of the ALA reflects the steady emergence of a philosophy within the entire library community. Although that philosophy exhibits some loose ends, its core grows firmer, based on a history of trial and error and forced response to a continually changing social climate. The philosophy is young, too young to be rooted in tradition, but gradually it has gained recognition as the substance of the total philosophy shaping library service in the United States.

Challenges and Issues Today

The major issues facing libraries today continue to focus on free and open access to information. The ALA continues to support a commitment to the right of unrestricted access to information and ideas, regardless of the communications medium. This commitment was confirmed most recently in regard to the Internet.

In February 1996, the Communications Decency Act (CDA) was signed into law by President Clinton as a way to keep "indecent" material from anyone under the age of 18. The act said that if anyone under 18 was allowed to view "indecent" material, the provider was subject to a fine of up to \$250,000 and/or up to 2 years in prison. The CDA placed librarians and libraries at risk because the term "indecent" was not defined, providing no guidelines for librarians. The ALA filed a lawsuit (*American Library Association v. U.S. Department of Justice*) in February 1996 challenging the CDA's constitutionality. It was later consolidated with, and decided under, a separate suit brought by the ACLU (*ACLU v. Reno*). The lawsuit argued three points: 1) Prohibiting material as "indecent" was unconstitutional because the term was vague and undefined. In addition, the act did not distinguish between the information needs of a five-year-old child and a 17-year-old in college. 2) Congress had not considered alternative ways that parents might protect their own children in their own home, for instance, by using filtering software. 3) The Internet is not a broadcast medium but is more like the print medium in that each person controls what they access.

In June 1996, a lower court declared the CDA unconstitutional. The government appealed, and in June 1997, the U.S. Supreme Court, by a 9-0 vote, held the CDA unconstitutional.

A unanimous Supreme Court decision notwithstanding, Congress went back to the drawing board. The second proposal was the Child Online Protection Act (COPA). In this attempt to circumvent the Supreme Court's CDA decision, Congress made two major changes: the "harmful to minors" standard replaced the "indecent" standard, and the focus was on "commercial" speech.

COPA also established a commission to study the effects of "inappropriate" material on children.

The sponsors believed these changes would save COPA from the fate of the Communications Decency Act, but the Third Circuit Court of Appeals in Philadelphia, the same court which handed down the original CDA decision (subsequently upheld by the Supreme Court), held COPA unconstitutional. The government, of course, appealed to the U.S. Supreme Court, and the Supreme Court heard the case on Wednesday, November 28, 2001.

The government's third attempt to control the Internet is the Children's Internet Protection Act (CIPA). CIPA requires libraries receiving certain types of federal funding to establish Internet safety policies and to use technology that blocks or filters material that is obscene, child pornography, or, when a minor is using the computer, "harmful to minors." This legislation once again puts librarians in an impossible position. Even filtering companies acknowledge that "technology" is incapable of making the fine distinction between legal speech and speech, which falls into these three and is not constitutionally protected.

On March 20, 2001, the American Library Association and several coplaintiffs filed suit, challenging the

Children's Internet Protection Act in the Third Circuit Court of Appeals. The case is scheduled to be heard in early 2002.

In addition to the ongoing debate over the Internet and filtering, there are a number of other issues facing libraries and librarians today. These include:

- Harassment, or a hostile work environment, produced by open access to the Internet.
- First Amendment rights of minors and their free access to information, as well as the attempt by some to mandate protection for minors from materials that may be "harmful to minors."
- Continued requests to libraries for patron records under the Freedom of Information Act. This has been of great concern to librarians in relation to new technology which can track a specific patron's Internet use.

The ALA continues to regularly develop resources to aid librarians in managing and communicating about the Internet. These include the *Libraries & The Internet Toolkit*. For the most current resources and the latest information, see the ALA Web site, which is updated and revised regularly.

CONCLUSION

Although the specific challenges will continue to evolve, the issues and principles remain the same. Librarians and libraries fulfill a unique role in our democratic society. Like no other group, we strive to preserve and protect free and open access to information for all who use our libraries. For, as James Madison explained: "A popular government, without popular information, or the mean of acquiring it, is but a prologue to a farce or a tragedy; or perhaps both. Knowledge will forever govern ignorance; and a people who mean to be their own governors must arm themselves with the power which knowledge gives."

Intelligence and Security Informatics

Hsinchun Chen

Zhenhua Lai

Yan Dang

Yulei Zhang

Department of Management Information Systems, University of Arizona, Tucson, Arizona, U.S.A.

Abstract

The tragic events of September 11, 2001, have had far-reaching effects on many aspects of U.S. society. Six critical mission areas, as suggested in the “National Strategy for Homeland Security” report, have been identified where information technology can contribute to safeguarding our national security. These areas include *intelligence and warning, border and transportation security, domestic counterterrorism, protecting critical infrastructure, defending against catastrophic terrorism, and emergency preparedness and responses*. Intelligence and Security Informatics (ISI) encompasses the development of advanced and socially responsible information technologies, systems, algorithms, and databases for national security related applications, through an integrated technological, organizational, policy-based, and privacy-preserving approach. This entry reviews current ISI research challenges and presents a research framework with a primary focus on knowledge discovery from databases (KDD) technologies. The framework is discussed in the context of crime types and security implications. In addition to the technical discussions, caveats for data mining and civil liberties concerns are also considered.

INTRODUCTION

The tragic events of September 11 have caused far-reaching changes to many aspects of society. Terrorism is one of the most significant threats to national security due to its potential of bringing massive damage to our infrastructure, economy, and people. In response to this challenge, federal authorities are actively implementing comprehensive strategies and measures in order to achieve the three objectives identified in the “National Strategy for Homeland Security” report:^[1] 1) preventing future terrorist attacks; 2) reducing the nation’s vulnerability; and 3) minimizing the damage and enabling recovery from attacks that occur. State and local law enforcement agencies, likewise, are becoming more vigilant about criminal activities, which can harm public safety and threaten national security.

Academics in the fields of natural sciences, computational science, information science, social sciences, engineering, medicine, and many others have also been called upon to help enhance the government’s abilities to fight terrorism and other crimes. Science and technology have been identified in the “National Strategy for Homeland Security” report as the keys to win the new counterterrorism war.^[1] Especially, it is believed that information technology will play an indispensable role in making our nation safer,^[2] by supporting intelligence and knowledge discovery through collecting, processing, analyzing, and utilizing terrorism- and crime-related data.^[3,4] Based on the crime and intelligence knowledge

discovered, federal, state, and local authorities can make timely decisions in selecting effective strategies and tactics as well as allocate the appropriate amount of resources to detect, prevent, and respond to future attacks.

PRIVACY VS. INFORMATION SHARING: A BROADER SOCIETAL ISSUE

To protect the United States from future terrorist attacks, various law enforcement and homeland security agencies must act proactively and collaboratively to thwart planned or future acts of aggression. Most government agencies involved in safeguarding national security create their own databases and other stores of information which relate to potential sources of threats. The sharing of such data stores has been widely proposed as a method for leveraging existing knowledge to better forecast possible attacks. However, these shared databases may be misused, and may violate the privacy rights and civil liberties of innocent citizens. Privacy is the ability of an individual or group to keep their lives and personal affairs out of public view, or to control the flow of information about them. It is considered by many to be one of the most fundamental rights of citizens in a modern society.

More than ever, information technologies have become more prevalent and overreaching in modern day, post-Internet society. Companies, organizations, and governments are using better databases, Internet applications, and information technologies to collect information about

their customers, employees, and citizens. Advanced data mining techniques have also been increasingly used by companies and governments to better understand their customers or citizens. These pervasive and powerful technologies are also beginning to adversely affect individual privacy. How can one tell what kind of data is being collected by whom, and for what purposes? How can one ensure that data are collected and used for, and only for, the intended purposes?

Many information misuses have been reported in popular news sources (e.g., identity theft reported in <http://law.jrank.org/pages/7469/Identity-Theft.html>). In one federal prosecution, the defendants allegedly obtained the names and social security numbers of U.S. military officers from a Web site. The defendants used more than 100 of those names and social security numbers to apply for a Delaware Bank credit card. The fraudulent credit card transaction cost the Delaware Bank millions of dollars in 2000. In another reported case in the Central District of California, a woman pleaded guilty for using a stolen social security number and filing for bankruptcy in the name of her victim. Because (digital) information can be easily collected, copied, transmitted, and (potentially) misused, information collectors' abilities to safeguard the data they collect is even more critical now.

Despite the clear need for maintaining individual privacy, governments and businesses may have reasons for accessing and sharing customer or citizen information. Many previous court cases have supported such uses. For example, in *Davis versus Freedom of Information Commission*, 259 Conn. 45 (2001) The Connecticut Supreme Court declared that the Drivers Privacy Protection Act (DPPA) does not prohibit other government agencies from receiving personal information from the State DMV in the course of their normal government functions. Similarly, in 2002, Nevada's highest court ruled that the incoming and outgoing calls on the public telephones are not considered to be protected information and may be used for other purposes. Clearly, privacy and information sharing will continue to raise serious debates for the foreseeable future.

INFORMATION TECHNOLOGIES AND NATIONAL SECURITY

As part of the post-9/11 national security programs in the United States, six critical mission areas have been identified where information technology can contribute to the accomplishment of the strategic national security objectives identified in the "National Strategy for Homeland Security" report:^[1]

- *Intelligence and warning.* Although terrorism depends on surprise to bring damage to targets,^[1] terrorist activities are neither random nor impossible to track. Terrorists must plan and prepare before the execution of

an attack by selecting a target, recruiting and training executors, acquiring financial support, and traveling to the country where the target is located.^[5] To avoid being preempted by authorities they may hide their true identities and disguise attack-related activities. Similarly, criminals may use falsified identities during police contacts.^[6] Although it is difficult, detecting potential terrorist attacks or crimes is possible and feasible with the help of information technology. By analyzing the communication and activity patterns among terrorists and their contacts (i.e., terrorist networks), detecting deceptive identities, or employing other surveillance and monitoring techniques, intelligence and warning systems may issue timely, critical alerts and warnings to prevent attacks or crimes from occurring.

- *Border and transportation security.* Terrorists enter a targeted country through an air, land, or sea port of entry. Criminals in narcotics rings travel across borders to purchase, carry, distribute, and sell drugs. Information, such as travelers' identities, images, fingerprints, vehicles used, and other characteristics, is collected from customs, borders, and immigration authorities on a daily basis. The collection can greatly improve the capabilities of counterterrorism and crime-fighting capabilities by creating a "smart border" where information from multiple sources is shared and analyzed to help locate wanted terrorists or criminals. Technologies such as information sharing and integration, collaboration and communication, biometrics, and image and speech recognition will be greatly needed to create smart borders across all ports of entry.
- *Domestic counterterrorism.* Because both international and domestic terrorists may be involved in local crimes, state and local law enforcement agencies are also investigating and prosecuting terrorism-related crimes. Terrorism, like gangs and narcotics trafficking, is regarded as a type of organized crime in which multiple offenders cooperate to carry out offenses. Information technologies that help find cooperative relationships between criminals and their interactive patterns are also helpful for analyzing terrorism. Monitoring activities of domestic terrorist and extremist groups using advanced information technologies will also likely to be helpful to public safety personnel and policy makers.
- *Protecting critical infrastructure and key assets.* Roads, bridges, water suppliers, and many other physical service systems are critical infrastructure and are key assets of a nation. They may become the target of terrorist attacks because of their vulnerabilities.^[1] Moreover, virtual (cyber) infrastructure such as the Internet may also be vulnerable to intrusions and inside threats.^[7] Criminals and terrorists are increasingly using cyberspace to conduct illegal activities, share ideology, solicit funding, and recruit. In addition to

physical devices such as sensors and detectors, advanced information technologies are needed to model the normal behaviors of the usage of these systems and then use the models to distinguish abnormal behaviors from normal behaviors. Protective or reactive measures can be selected based on the results to secure these assets from attacks.

- *Defending against catastrophic terrorism.* Terrorist attacks can cause devastating damage through the use of chemical, biological, or radiological weapons. Biological attacks, for example, may cause contamination, infectious disease outbreaks, and significant loss of life. Information systems that can efficiently and effectively collect, access, analyze, and report data about catastrophe-leading events can help prevent, detect, respond to, and manage these attacks.^[8]
- *Emergency preparedness and responses.* In case of a national emergency, prompt and effective responses are critical to reducing the damage resulting from an attack. In addition to the systems that are prepared to defend against catastrophes, information technologies that help design and experiment optimized response plans,^[9] identify experts, train response professionals, and manage consequences are beneficial for both planning and emergency response. Moreover, information systems that facilitate social and psychological support to the victims of terrorist attacks can also assist disaster recovery efforts.

PROBLEMS AND CHALLENGES

Although it is important for the critical missions of national security, the development of information technology for counterterrorism and crime-fighting applications faces many problems and challenges. Currently, intelligence and security agencies are gathering large amounts of data from various sources. Processing and analyzing such data, however, have become increasingly difficult tasks. Treating terrorism as a form of organized crime allows the categorization of these challenges into the following types:

- *Characteristics of criminals and crimes.* Crimes can be geographically diffused and temporally dispersed. In organized crimes such as transnational narcotics, the trafficking criminals often live in different cities, states, or even countries. Drug distribution and sales occur in different places at different times. Similar situations exist in other organized crimes (e.g., terrorism, armed robbery, and gang-related crime). As a result, investigations must cover multiple offenders who commit criminal activities in different places at different times. This can be fairly difficult given the limited resources that most intelligence and security

agencies have. Moreover, as computer and Internet technologies advance, criminals are utilizing cyberspace to commit various types of cyber-crimes under the disguise of ordinary online transactions and communications.

- *Characteristics of crime and intelligence related data.* A significant source of challenge is information stovepipe and overload resulting from diverse data sources, multiple data formats, and large data volumes. Unlike other domains such as marketing, finance, and medicine in which data can be collected from particular sources (e.g., sales records from companies, patient medical history from hospitals), the intelligence and security domain does not have a well-defined data source. Both authoritative information (e.g., crime incident reports, telephone records, financial statements, immigration and custom records) and open-source information (e.g., news stories, journal articles, books, Web pages) need to be gathered for investigative purposes. Data collected from these different sources often are in different formats ranging from structured database records to unstructured text, image, audio, and video files. Important information such as criminal associations may be available but contained in unstructured, multilingual texts and can therefore remain difficult to access and retrieve. Moreover, as data volumes continue to grow, extracting valuable and credible intelligence and knowledge becomes a difficult problem.
- *Characteristics of crime and intelligence analysis techniques.* Current research on the technologies for counterterrorism and crime-fighting applications lacks a consistent framework for addressing the major challenges. Some information technologies including data integration, data analysis, text mining, image and video processing, and evidence combination have been identified as being particularly helpful.^[2] However, the question of how to employ them in the intelligence and security domain and use them to effectively address the critical mission areas of national security (with proper protection of privacy and civil liberties) remains unanswered and requires further research.

AN ISI RESEARCH FRAMEWORK

“Intelligence and Security Informatics” (ISI)^[3,4,10] is a multidisciplinary science with its main objective being the “development of advanced and socially responsible information technologies, systems, algorithms, and databases for national security-related applications, through an integrated technological, organizational, policy-based, and privacy-preserving approach.” ISI has at its core a focus on developing and employing computationally intensive techniques with the goal of increasing current levels of

national security through an integrated approach that takes into account organizational considerations; national security priorities; laws, regulations, and policies; and privacy protection. This next section presents a research framework with a primary focus on knowledge discovery from databases (KDD) technologies, and is discussed in the context of crime types and security implications.

Crime is an act or the commission of an act that is forbidden, or the omission of a duty that is commanded by a public law and that makes the offender liable to punishment by that law. The more threat a crime type poses to public safety, the more likely it is to be of national security concern. Some crimes, such as traffic violations, theft, and homicide, are primarily in the jurisdiction of local law enforcement agencies. Other crimes need to be dealt with by both local law enforcement and national security authorities. Identity theft and fraud, for instance, is relevant at both the local and national levels—criminals may escape arrest by using false identities, or drug smugglers may enter the United States by holding counterfeited passports or visas. Organized crimes such as terrorism and narcotics trafficking often diffuse geographically, resulting in common security concerns across cities, states, and countries. Cyber-crimes can pose threats to public safety across multiple jurisdictional areas due to the widespread nature of computer networks. Table 1 summarizes the different types of crimes sorted by the degree of their respective public influence.^[4] International and domestic terrorism, in particular, often involves multiple crime types (e.g., identity theft, money laundry, arson and bombing, organized and violent activities, and cyber-terrorism) and has the potential to cause enormous damage.

KDD techniques can play an important role in improving counterterrorism and crime-fighting capabilities of intelligence, security, and law enforcement agencies by reducing cognitive and information overload that results from dealing with massive amounts of data. Knowledge discovery refers to the nontrivial extraction of implicit,

previously unknown, and potentially useful knowledge from data. Knowledge discovery techniques promise easier, more convenient, and practical exploration of very large collections of data for organizations and users, and have been applied in marketing, finance, manufacturing, biology, and many other domains (e.g., predicting consumer behaviors, detecting credit card frauds, or clustering genes that have similar biological functions).^[11] Traditional knowledge discovery techniques include association rule mining, classification and prediction, cluster analysis, and outlier analysis.^[12] As natural language processing (NLP) research advances, text mining approaches that automatically extract, summarize, categorize, and translate text documents have also been widely used.

Many of these KDD technologies can be applied in ISI studies.^[3,4] Existing ISI technologies can be categorized into six classes: *information sharing and collaboration*, *crime association mining*, *crime classification and clustering*, *intelligence text mining*, *spatial and temporal crime mining*, and *criminal network mining*. These six classes are grounded on traditional knowledge discovery technologies, but with new approaches added, including spatial and temporal crime pattern mining and criminal network analysis, which are more relevant to counterterrorism and crime investigation. In addition, new research has begun in the areas of privacy-preserving, security-aware data integration and data mining. Although information sharing and collaboration are not data mining per se, they help prepare, normalize, warehouse, and integrate data for knowledge discovery and thus are included in the framework.

Fig. 1 presents the proposed research framework, showing crime types and the six classes of techniques useful for (or showing the promise of utility to) the investigation of the various crime types.^[4] The crime data mining techniques are listed, from bottom to top, in an increasing scale of analysis capability. Note that more serious crimes—those inducing greater public harm—may require a more complete set of knowledge discovery

Table 1 Crime types and security concerns.

Crime types		
Type	Local law enforcement level	National security level
Traffic violations	Driving under influence (DUI), fatal/personal injury/property damage, traffic accident, road rage	—
Sex crime	Sexual offenses, sexual assaults, child molesting	Organized prostitution, people smuggling
Theft	Robbery, burglary, larceny, motor vehicle theft, stolen property	Theft of national secrets or weapon information
Fraud	Forgery and counterfeiting, fraud, embezzlement, identity deception	Transnational money laundering, identity fraud, transnational financial fraud
Arson	Arson on buildings, apartments	
Organized crime	Narcotic drug offenses (sales or possession), gang-related offenses	Transnational drug trafficking, terrorism (bioterrorism, bombing, hijacking, etc.)
Violent crime	Criminal homicide, armed robbery, aggravated assault, other assaults	Terrorism
Cyber crime	Internet fraud (e.g., credit card fraud, advance fee fraud, fraudulent Web sites), illegal trading, network intrusion/hacking, virus spreading, hate crimes, cyber-piracy, cyber-pornography, cyber-terrorism, theft of confidential information	

	Crime Types							
Crime Data Mining Techniques	Traffic Violation	Sex Offense	Theft	Fraud	Arson	Organized Crime	Violent Crime	Cyber Crime
Criminal Network Analysis						X	X	X
Spatial and Temporal Pattern Mining				X		X	X	X
Text Mining		X	X	X	X	X	X	X
Classification & Clustering	X	X	X	X	X	X	X	X
Association	X	X	X	X	X	X	X	X

Fig. 1 A knowledge discovery research framework for ISI.

techniques. For example, the investigation of organized crimes such as terrorism may depend on criminal network analysis technology, which requires the use of other knowledge discovery techniques such as association mining and clustering. An important observation about this framework is that the high-frequency occurrences and strong association patterns of severe and organized crimes such as terrorism and narcotics trafficking present a unique opportunity and potentially high rewards for adopting such a knowledge discovery framework.

Some of these classes of data mining techniques are of great relevance to ISI research. *Text mining* is critical for extracting key entities (people, places, narcotics, weapons, time, etc.) and their relationships presented in voluminous police incident reports, intelligence reports, open-source news clips, etc. Some of these techniques need to be multilingual in nature, including the abilities to employ machine translation and cross-lingual information retrieval (CLIR). *Spatial and temporal mining and visualization* is often needed for geographic information systems (GIS) and temporal analysis of criminal and terrorist events. Most crime analysts are well trained in GIS-based crime mapping tools; however, automated spatial and temporal pattern mining techniques (e.g., hotspot analysis) have not been widely adopted in intelligence and security applications. Organized criminals (e.g., gangs and narcotics) and terrorists often form interconnected covert networks to carry out illegal activities. Often referred to as “dark networks,” these organizations exhibit unique structures, communication channels, and resilience to attack and disruption. New computational techniques including social network analysis, network learning, and network topological analysis (e.g., random network, small-world network, and scale-free network) are needed for the systematic study of those complex and covert networks. These techniques are classified under *criminal network analysis* in Fig. 1.

ISI, CIVIL LIBERTIES, AND DATA MINING

The U.S. Constitution and its Bill of Rights were drafted in part to define and protect the civil liberties of United

States citizens and to set limits on the government’s power. Important civil liberties include freedom of association, freedom of assembly, freedom of speech, and the right to privacy. In the United States, the American Civil Liberties Union (ACLU) is a powerful advocacy group that aims to ensure the protection of free speech, privacy, and other fundamental human rights.

The potential negative effects of intelligence gathering and analysis on the privacy and civil liberties of the public have been well publicized.^[13] There exist many laws, regulations, and agreements governing data collection, confidentiality, and reporting, which could directly impact the development and application of ISI technologies. Intelligence and security agencies and ISI researchers must be aware of these laws and regulations in research and practice. The use of a hypothesis-guided, evidence-based approach in crime and intelligence analysis research can also help assure that privacy is appropriately respected. For example, there should be probable and reasonable causes and evidence for targeting particular individuals or data sets for analysis. Proper investigative and legal procedures need to be strictly followed. It is neither ethical nor legal to “fish” for potential criminals from diverse and mixed crime, intelligence, and civilian related data sources. The well-publicized Defense Advanced Research Program Agency (DARPA), Total Information Awareness (TIA) program, and the Multi-State Anti-Terrorism Information Exchange (MATRIX) system, for example, have been shut down by the U.S. Congress due to their potential misuse of citizen data and impairment of civil liberties.^[14]

However, other initiatives have been maintained, as the catastrophic 9/11 events had a profound impact on the way the U.S. government acts on security concerns. In response to the attacks, for example, the U.S. government enacted the USA PATRIOT Act, created the Department of Homeland Security (DHS), increased security efforts and airports and other ports of call, etc.

The PATRIOT Act expands the government’s ability to examine records on an individual’s activity whether those records are being held by third parties or were acquired by secret searches and/or wiretap surveillance. The Act expands a narrow exception to the Fourth Amendment that

had been created for the collection of foreign intelligence information and also expands another Fourth Amendment exception for spying that collects “addressing” information about the origin and destination of communications. An immediate result of the events of September 11, 2001 was the extraordinarily rapid passage of the USA PATRIOT Act in late 2001. The legislation was passed by the Senate on October 11, 2001 and by the House on October 24, 2001; it was signed by the President on October 26, 2001, with some revisions following in 2005 and 2006. But the continuing legacy of the then-existing consensus and the lack of detailed debate and considerations have created an ongoing national argument as to the proper balance between national security and civil liberties.

FUTURE DIRECTIONS

National security research poses unique challenges and opportunities. Much of the established data mining and knowledge discovery literature, findings, and techniques need to be reexamined in light of the unique data and problem characteristics in the law enforcement and intelligence community. New text mining, spatial and temporal pattern mining, privacy-preserving data mining, and criminal network analysis of relevance to national security are among some of the most pressing research areas. However, researchers cannot conduct research in a vacuum. Partnerships with local, state, and federal agencies need to be formed to obtain relevant test data and necessary domain expertise and feedback for ISI research.

International and Comparative Librarianship

Peter Johan Lor

School of Information Studies, University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, U.S.A., and Department of Information Science, University of Pretoria, Pretoria, South Africa

Abstract

The concepts of international librarianship and comparative librarianship first appeared under their respective titles in the 1950s, when their literatures were overlapping. During the 1960s, and continuing through the 1980s, much energy was devoted to defining each of them and attempting to distinguish between them. Although clearer definitions were developed during the mid-1970s by J. Stephen Parker and J. Periam Danton respectively, some confusion has persisted. In practice the two fields are often grouped together as “international and comparative librarianship” or “international and comparative library science.” Nevertheless, the two fields can and should be distinguished. This entry attempts to articulate the definition and scope of each, outlines some methodological issues, and surveys the development of the literature.

INTRODUCTION

In today's globalized knowledge society international relations and resource sharing among libraries and the exchange of knowledge among librarians are indispensable. Historically librarianship has had a significant international dimension, dating back to the ancient Library of Alexandria, which maintained a policy of attempting to collect all the world's knowledge. During that time, according to a possibly apocryphal tradition, visiting ships from foreign ports were required to surrender books for copying by the Library's scribes.^[1] This method hardly serves as an example for library cooperation today, but does illustrate that librarianship has an inherently international outlook. During the late nineteenth century this international dimension took on a more meaningful shape in the form of international conferences of librarians, bibliographers, and book lovers, resulting in the establishment of the first international organizations for those groups. International librarianship and comparative librarianship first appeared under their respective names in the 1950s, and their literatures continued to overlap during the 1960s through the 1980s, during which time much energy was devoted to defining each and attempting to distinguish between them. Clearer definitions were developed during the mid-1970s by J. Stephen Parker^[2] and J. Periam Danton^[3] respectively. However, some confusion persists. In practice the two fields are often grouped together as “international and comparative librarianship” or “international and comparative library science.” Nevertheless, the two fields can and should be distinguished. In an attempt to clarify the distinctions, this entry discusses the definition and scope of international librarianship and comparative

librarianship, outlines some methodological issues, and surveys the development of the literature.

DEFINITIONS AND SCOPE

International Librarianship

The origins and early definitions of international librarianship have been articulated by Danton,^[3,4] Parker,^[2] Harvey,^[5] and Keresztesi.^[6] Some recent contributions and further clarifications have been attempted by Sami,^[7] Bliss,^[8] Liu,^[9] and Lor.^[10] However, Parker's definition has been widely cited and it serves as an authoritative point for discussion:

International librarianship consists of activities carried out among or between governmental or non-governmental institutions, organizations, groups or individuals of two or more nations, to promote, establish, develop, maintain and evaluate library, documentation and allied services, and librarianship and the library profession generally, in any part of the world. (p. 221)^[2]

Several key points for consideration are raised by the definition:

1. International librarianship is a field of *activity*, rather than a scientific discipline. This does not, of course, prevent the activities from being studied with scientific rigor. In this case the field may be referred to as “international library science,” particularly as practiced in the United States, where the term “library science” is used to refer to the field as a scientific discipline.

2. The activities are conducted in a *relationship* “among or between” parties at various levels, ranging from individuals to governments. Such activities, among others, include resource sharing, standardization, development aid, political and cultural influences, relations between and/or among national associations, and exchanges of staff, students, and scholars.
3. These parties are located in *two or more nations* (countries). This stipulation raises the question of what is meant by “international.” Strictly speaking, relations between two countries are referred to as “bilateral” and purists would restrict the use of the term “international” to refer to relations between more than two countries,^[6] but in international librarianship this distinction is seldom observed.

This last point requires some elaboration. In the United States the term “international” is often used to mean “foreign,” hence the use of the term “international librarianship” to mean “librarianship in other countries.” This designation is common in the literature, where books bearing titles that include the term “international librarianship” may be, in fact, collections of articles describing aspects of librarianship in countries other than the United States. Such literature has been classified by Harvey as “foreign library science,” which he defined as being “the description of any aspect of library operations in one or more countries other than the author’s own country.”^[11] The notion of “foreign” librarianship has been criticized, notably by Danton,^[3,4] who points out that what is foreign depends on one’s nationality. To illustrate: an article on school libraries in Tunisia written by a Tunisian might be considered by American readers—but not by Tunisian readers—to be foreign librarianship. Conversely, how would American readers classify an article on American school libraries written by a Tunisian? Therefore, the notion of foreign librarianship will always be relative to the nationalities of authors and readers and it would be impossible to delimit the corpus of writings on the subject. Lor^[10] argues that to qualify as a contribution to international librarianship a book or article should not merely describe conditions in another country. There should be an international dimension in terms of relationships between countries, influences of one country on another, etc. In practice this requirement is often ignored. There is some merit in the argument that an author from one country may bring fresh insights to library conditions in another country and therefore the work qualifies to be regarded as a contribution to international librarianship. The well-known book of the Norwegian librarian, Wilhelm Munthe,^[12] on American librarianship is often cited as such an example.

The activities of international organizations are also generally included within international librarianship.^[6,13]

The promotion of library development by UNESCO is an example. Some writers would also include the library and information services of such bodies as part of the scope of international librarianship. However, this does not easily fit within Parker’s definition.

Comparative Librarianship

During the 1960s and 1970s the origins and definitions of comparative librarianship were discussed by various writers, including Foskett,^[13,14] Shores,^[15,16] Simsova and MacKee,^[17,18] Collings,^[19] Harvey,^[11] and Yayakuru.^[20] Having systematically reviewed all prior attempts to define comparative librarianship and delimit its scope, J. Periam Danton in 1973 formulated what remains the most authoritative and appropriate definition of the field to date. He states that comparative librarianship is an

area of scholarly investigation and research (that) may be defined as the analysis of libraries, library systems, some aspect of librarianship, or library problems in two or more national, cultural or societal environments, in terms of socio-political, economic, cultural, ideological, and historical contexts. This analysis is for the purpose of understanding the underlying similarities and differences and for determining explanations of the differences, with the ultimate aim of trying to arrive at valid generalizations and principles. (p. 52)^[3]

Danton, later slightly amended his definition (p. 4).^[4] Both of his contributions emphasize three essential aspects of comparative librarianship:

1. There has to be a “cross-societal or cross-cultural element.” Often this is cross-country or international, but the comparison can be conducted within a single country, provided that the societal, cultural, or ideological differences are such that they can give rise to differences in the nature of the library as an institution. Hence a comparison of public libraries in the German, French, and Italian speaking cantons of Switzerland can legitimately be classified as comparative librarianship, but a comparison of the library use of working class and middle class Britons would not. On this point opinions diverge. While Danton, basing his position on the example of disciplines such as comparative education, comparative law, and comparative sociology, insists on the cross-societal, cross-cultural, or cross-country element, other writers such as D.J. Foskett,^[13] Simsova and MacKee,^[17,18] Sami,^[7] and Lor^[10] open the door to comparisons that are not cross-societal or cross-cultural in scope. The danger of this approach is that, since comparisons are inherent in much empirical research, the greater part of research in library science could be labeled as “comparative librarianship.”

2. There have to be “actual comparisons,” which go beyond mere descriptions or juxtaposition of data. Comparison implies the analysis of the similarities and differences in the sets of data collected.
3. An attempt should be made to explain the observed similarities and differences with a view to building theory.^[4] Thus comparative librarianship is described as a discipline which employs a rigorous scientific methodology, on the pattern of other, older comparative disciplines such as comparative education.

Distinction between International and Comparative Librarianship

As Danton^[4] pointed out, a considerable literature about the definitions of international and comparative librarianship arose more or less at the same time that Parker's definition of international librarianship and Danton's own definition of comparative librarianship appeared. The result is a literature in which there is much discussion but no clear consensus on the distinction between international librarianship and comparative librarianship. Attempts to distinguish between the two have generally taken one or more of the following approaches:

- Hierarchical: comparative librarianship is a species of the genus international librarianship or vice versa.^[9] For example, Harvey subsumes “comparative library science” (along with “foreign library science” and “international institutional library science”) under “international library science” (pp. 296–297).^[11] Krzys, Litton, and Hewitt subsume both “international library science” and “comparative library science” under “world library science.”^[21] Against this it has to be pointed out that attempts to impose such hierarchical relationships are problematic if the concepts belong to different categories: “international” denotes a geographic scope, whereas “comparative” denotes a methodology.
- Study–Activity: comparative librarianship is the scientific study, while international librarianship is the field of professional activity, often conceived in a rather soft and idealistic manner as aiming to promote international understanding and cooperation.^[22] A more rigorous distinction was made by Miles Jackson:

International librarianship is limited strictly to those activities that involve librarianship and all its aspects across national boundaries. It would thereby exclude comparative analysis, but include such activities as exchange of librarians, books, ideas, and the study of the library systems in different countries. . . comparative librarianship should lean on the tradition of comparative studies found in other fields such as political, government and legal studies.^[23]

Against this it should be pointed out that the “activities” included under international librarianship can and should also be subjected to systematic and rigorous investigation.

- Subject–Methodology: international librarianship is the subject field while comparative librarianship is the methodology. Collings states that comparative librarianship is a “scholarly method of investigation.”^[19] Keresztesi has stated that “comparative librarianship is essentially a method of enquiry” (p. 437).^[6] Against this it has to be pointed out that more than one methodology can be used to study international librarianship. Parker describes comparative librarianship as a tool, the most appropriate one, for international librarianship.^[2] However, it is not the only tool.

In practice the terms “international librarianship” and “comparative librarianship” are often used interchangeably or in combination, as in “international and comparative librarianship.” This combination of subject matter is also taught under this name in five of the nine U.S. library schools that offer courses related to international and/or comparative librarianship as surveyed by Liu and Cheng in a book tellingly entitled *International and comparative studies in information and library science*.^[24] Nevertheless, the two can and should be clearly distinguished. Concluding a review of the discussion up until 1977, Danton challenged the profession to stop writing *about* comparative librarianship and to start *doing* it.^[4] In this spirit no new definitions are offered here. Instead, the definitions of international librarianship by Parker and of comparative librarianship by Danton, cited above, are endorsed. In any case, discussions of definitional issues have become less frequent since the 1970s.

METHODOLOGY

International Librarianship

In contrast to that of comparative librarianship, much of the literature of international librarianship lacks methodological rigor. It tends to be descriptive rather than analytical. This is particularly true of the genre of “foreign librarianship,” much of which is anecdotal and based on personal experience. Such publications, however, should not be overlooked as primary source material for more rigorous research, as they may be useful not only for descriptions of particular contemporary situations, but also for what it reveals of the attitudes of the writers. The literature of international librarianship as distinct from comparative librarianship is generally descriptive in nature and derives its data from sources such as

- Literature (both published and unpublished, e.g., government statistical reports, annual reports and Web sites of libraries and other organizations, project reports, autobiographical materials).
- Observation (e.g., study tours, reports by participants in exchange programs, or by aid workers assisting in library development programs).
- Interviews (including telephonic interviews).
- Questionnaire surveys (with increasing use being made of Web-based surveys).

Comparative Librarianship

The methodology of comparative librarianship has been described by a number of authors, with a strong emphasis on methodological rigor. Early contributions by Simsova and McKee^[17] and Danton^[3] are frequently cited, although Parker pointed out that their proposals were largely untested and untried.^[2] Collings distinguished three major types of studies: area studies, cross-national or cross-cultural studies, and case studies, and outlined the primary and secondary sources for such studies.^[19] Harvey put forward a “general comparative research methodology,” comprising 12 stages, starting with a speculative stage and proceeding through description, analysis and comparison and interpretation, correlation and extension, to prediction, the evolution of new theories and the formulation of laws.^[11] This is very much in accordance with the approach of the positivist social science and educational research methodology texts of that period, e.g., Van Dalen,^[25] which emphasized the painstaking assembling of small empirical building blocks in the quest for the holy grail of science: universal scientific laws. Harvey also usefully outlines the research techniques that can be used in comparative librarianship, including “statistical comparisons, problem analyses, trend identification, factorial and analytical approaches, analysis against norms, developmental criteria identification and historical analyses” (pp. 307–308).^[11] Krzys, Litton, and Hewitt put forward an impressive research program for “world librarianship.”^[21] Liu describes a cooperative methodology to conduct cross-country comparisons, involving the collaboration of experts in both countries.^[26] Danton stressed the interdisciplinary nature of comparative librarianship.^[3] This is hardly surprising, considering the cross-national, cross-cultural, or cross-societal nature of such studies.

The basic elements of the comparative method are

- The identification of a research problem. The problem should be of a significant rather than trivial nature. There is more to be learned from a study on the selection of Arabic name authorities in Egypt and Iran than from a study of the shape and size of catalog cards formerly used in these two countries.
- The selection of a suitable theoretical framework. This is important for guiding the subsequent steps.

- The formulation of research questions or hypotheses.
- The selection of two or more systems (or processes, institutions, situations, etc.) for study. There should be sufficient underlying commonality (e.g., in terms of types of libraries, materials, or processes) to make the comparison worthwhile. There is little point in comparing children’s libraries in Norway with young adult services in Wales.
- The collection of data on the systems. The data may be derived from available case studies, area studies, or descriptive studies, such as are typically found in the literature of international librarianship, or they may be collected by means of surveys, interviews, observation, etc., specifically for the purpose of the comparative study.
- The processing, classification, tabulation, and juxtaposition of the collected data. An interesting example of developing a classification scheme for categorizing the data of an international comparative study is found in Rochester and Vakkari.^[27]
- The analysis undertaken to search for patterns of similarities and differences in the sets of data and to reveal their causes, this process being guided by the research questions, or if hypotheses have been formulated, taking the form of the formal testing of these. This is a critical step. If it is missing, the study is not truly comparative.
- The discussion and interpretation of the findings in relation to the theoretical framework in order to further develop and generalize the theory.

LITERATURE AND THEMES

There is a considerable literature on international librarianship, which is difficult to separate from the less extensive literature of comparative librarianship. Much of the literature of international librarianship falls in the category of foreign librarianship: descriptions of library conditions in countries other than that of the author or editor. This ongoing category can be regarded as the wallpaper or background to the literature of international librarianship proper. In this section a necessarily impressionistic overview of themes is presented in a roughly chronological order.

Origins and Early Development

Interest in international librarianship is not a new phenomenon. The American Library Association (founded in 1876) and the (British) Library Association (founded in 1877) engaged in international activities at an early stage. Initially these mainly took the form of representation at each other’s conferences and at those of other national associations, but in the first decade of the twentieth century cooperation between the United States and the United

Kingdom was manifested more concretely in the adoption of the Anglo-American cataloging rules of 1908.^[28] The International Institute of Bibliography, which later became the International Federation for Information and Documentation (FID), was founded in 1895, while the International Federation of Library Associations and Institutions (IFLA) was founded in 1927 in close association with the League of Nations. The early leaders of IFLA were inspired by ideals of world-wide peace and cooperation.^[29] A pioneering work of this period was Wilhelm Munthe's *American Librarianship from a European Angle*, published in 1939.^[12]

The first recorded use of the term "comparative librarianship" occurred in 1954, in two articles by Chase Dane.^[30,31] The early literature on this new field, reviewed by Danton,^[3] exhibited an idealistic and affective dimension, emphasizing its value for enhancing international understanding and also its practical value for furthering library cooperation and development, for example in Dane,^[31] Shores,^[16] and Collings.^[19] As already noted, much energy was expended on largely inconclusive attempts to define the field and distinguish it from international librarianship. Writers on comparative librarianship drew much inspiration from writers on other comparative disciplines, such as comparative education, for example Fraser and Brickman.^[32]

The term "international librarianship" also appears to date from after the Second World War, being used by Peter Havard-Williams in 1959.^[33] As with comparative librarianship, much of the literature of this period reflects normative, moral, or idealistic concerns, such as internationalism, the striving for international peace and tolerance, and international cooperation.

The 1960s and 1970s

In the first decades following World War II the influence of UNESCO was strong and the *UNESCO Bulletin for Libraries*, since discontinued, was an important medium for the field. The post-war emergence of independent states in Asia and Africa aroused much interest among internationally minded librarians^[34] and gave rise to idealistic and ambitious plans for developing national library services. The work of foreign cultural and aid agencies, for example the work of the British Council in developing national library services in former British colonies, featured in the literature, sometimes in descriptive accounts, at other times more critical observations. By that time professionals in developing countries, including Wijasuriya, Lim, and Nadaradha^[35] were warning of the challenges facing the extension of library services to their various countries' peoples. UNESCO's own work in library development in the developing world, which emphasized the importance of libraries for education, was an important theme, as were its efforts to promote the adoption of national information policies in these

countries: primarily the UNISIST (World Science Information System) and NATIS (National Information Systems) programs.^[2,33] UNESCO promoted the international exchange of publications, which was a significant activity for countries lacking foreign exchange. UNESCO's role as a partner and sponsor of IFLA programs was also important. The development of specialized international indexing and abstracting services such as MEDLARS (for medicine), AGRIS (for agriculture) and INIS (for nuclear science and technology) generated much literature of an international character.

The 1960s and 1970s were also years of theoretical reflection on the purpose, scope, and methodology of comparative librarianship; most of the sources cited in the above section on "Definitions and Scope" date from this period. A number of highly regarded comparative studies were published during this period, including a comparative study of public library development in France, Great Britain, and the United States by Jean Hassenforder^[36] and Frank Gardner's comparative study of public library legislation.^[37] Excellent single-country studies, while not strictly part of comparative or international librarianship, also appeared during this period. Those include Ferguson's *Libraries in France*,^[38] which appeared in Clive Bingley's Comparative Library Studies series, and Maack's *Libraries in Senegal*.^[39]

Throughout the post-war period, and particularly from the late 1960s, when IFLA adopted deliberate policies of reaching out to a potential membership outside Europe and North America, IFLA featured prominently in the literature of international librarianship.^[40] The *IFLA Journal* remains an important source of material in the field. IFLA's work in international library cooperation, especially its programs of Universal Bibliographic Control (UBC) and Universal Access to Publications (UAP) were promoted in its publications and in the writings of leaders, such as Maurice B. Line, who wrote dozens of articles promoting UAP. As information and communication technology developed in the 1970s and 1980s "library cooperation on an international scale (p.172)"^[33] became increasingly feasible, and the early notions of cooperation were progressively extended to resource sharing and networking. The MARC format, developed in the United States, soon became an international standardization phenomenon, generating national variants and international cooperation in the development of library catalogs, union catalogs, and national bibliographies. This also stimulated international cooperation in respect to cataloging rules, standards such as the international standard bibliographic descriptions (ISBDs), and the fundamental principles of cataloging, as expressed more recently in the *Functional requirements for bibliographic records* (FRBR) and related principles for authority records.

Other international nongovernmental organizations such as the FID (which was dissolved in 2002) have also

provided forums for international cooperation, discussion, and reflection, adding to the literature, and themselves featuring in it. Beginning in the 1950s various specialized international associations such as IAML (International Association of Music Libraries) and IBBY (the International Board on Books for Young People) were established, as were regional bodies such as ACURIL (Association of Caribbean Research, University and Institutional Libraries), CONSAL (Congress of Southeast Asian Librarians) and SCECSAL (Standing Conference of East, Central and Southern African Library and Information Associations). The growth of international associations has been attributed to greater international awareness following the Second World War, and to the advent of regular, affordable air transportation^[41]—it was no longer necessary for delegates to spend a week or more on board an ocean liner to attend an international conference.

From the 1980s to the Current Scene

In the 1980s and 1990s there was increasing emphasis on the impact of information for development.^[42] In a significant number of developing countries well-intentioned, Western-inspired library development programs had begun to falter. Starting in the 1970s a critical reevaluation of these post-colonial efforts, sometimes referred to as “cultural imperialism” (p. 7),^[13] got under way, as is described, for example, in seminal works such as *The Quiet Struggle: Information and Libraries for the People of Africa*, by Sturges and Neil^[43] and Gassol de Horowitz’s *Librarianship: A Third World Perspective*,^[44] as well as in contributions by younger African librarians such as Kingo Mchombu.^[45,46] During the 1980s questions were increasingly raised about international aspects of education for librarianship. These concerns related to the appropriateness of Western, particularly the United States and British, as well as East European models of content, curricula, and qualifications in developing countries.^[47] Concern was also expressed about the internationalization of library school programs, particularly in the United States.^[8,48]

In spite of the critical questions, a number of governmental aid agencies, particularly those of the United States, Canada, Great Britain, and the Nordic countries, have continued to play a significant role in supporting library development in the developing countries, as have a number of foundations such as the Andrew W. Mellon Foundation, the Carnegie Corporation of New York, and the Bill and Melinda Gates Foundation in the United States, and the Open Society Institute in Europe. These donors increasingly emphasize accountability and the sustainability of projects. This has stimulated programs aimed at capacity building by providing training opportunities for future leaders of the library profession in developing countries, such as those of the

Mortenson Center for International Library Programs at the University of Illinois at Urbana-Champaign, the Goethe Institut (Germany) and the Jay Jordan IFLA/OCLC Early Career Fellowship program of OCLC in partnership with IFLA.

Since the mid-1990s the economic, political, and ethical aspects of the international flow of information, particularly between developed countries and developing countries, have emerged as an important theme. The gap between rich and poor countries is often referred to as the “digital divide.” However, it is not merely digital, as it has significant political, legal, and economic dimensions. Librarians have become increasingly aware of the impact on their institutions and users of decisions on intellectual property and related matters that are taken at international forums such as the World Summit on the Information Society (WSIS), the World Trade Organization (WTO), the World Intellectual Property Organization (WIPO), and in multilateral or bilateral trade agreements between countries.^[49,50] In addition, issues of freedom of access to information and freedom of expression,^[51] and vexed questions of tolerance in multicultural environments have come to prominence at the international level as a consequence of increasing globalization.^[52] Advocacy has become a key activity of IFLA, which represents libraries and librarians internationally, often in partnership with other national and international organizations such as the (US) Library Copyright Alliance, the European Bureau of Library, Information and Documentation Associations (EBLIDA), and Electronic Information for Libraries (eIFL). Only through cooperation and continuous monitoring is the library profession able to ensure representation at the plethora of international meetings and to keep abreast of the huge volume of documentation generated by the international organizations. Currently, most of this documentation is disseminated through the Internet. Globalization has seen to it that the international affairs relevant to library professionals have multiplied to an extent that could not be foreseen by their predecessors. To many practicing librarians much of this may seem remote, but continuing vigilance is called for. It is therefore important to raise awareness of international issues in the profession.

It is an ongoing challenge to ensure that libraries are not taken for granted or ignored in international programs to promote the information society. In recent years the attention paid by UNESCO to libraries as such has decreased in favor of more general information society issues and the use of information technology. However, themes such as documentary preservation, access to knowledge, information literacy, and information ethics fortunately remain on the agenda of UNESCO’s Sector V (Information and Communication) and its Information for All Program (IFAP), while other UNESCO sectors concern themselves with literacy and book development. In all these areas librarians need to cooperate strategically in

advocating for libraries as key agencies in the information or knowledge society.

At the immediately practical level matters such as international bibliographic standardization, international document supply, collection development and services in area studies, and international aspects of human resource development (study abroad, job exchanges, working in foreign libraries, etc.) continue to form part of the literature of international librarianship.

In the 1980s a steady stream of contributions to comparative librarianship developed and this swelled as young researchers discovered a fruitful field for Ph.D. dissertation topics. The problem or thematic approach (in which library types, processes, problems, etc. in two or more countries are compared, as distinct from whole-country comparisons) is predominant. Library education and training seems to be the most popular area, followed by developing countries, school libraries, national information infrastructures (replacing the national information *policies* of the 1980s), various aspects of management (including evaluation, measurement, and statistics), and library and information science (LIS) research. General trends in LIS literature are reflected in that of international librarianship. For example, since the turn of the century the digital divide and issues of access to digital resources, and information literacy have come into prominence. Among developing regions the Far East attracts most attention;^[24] here the number of comparative studies in which various library practices in the United States and China are compared reflects the relatively large number of postgraduate students from China preparing Ph.D. dissertations in the United States.

CONCLUSION

International librarianship is an extensive and growing field of activity with an extensive body of literature. However, compared with that of comparative librarianship, its literature is largely practical, discursive, and descriptive, and lacks a theoretical basis. The literature of comparative librarianship, although smaller, is also growing. Much effort was expended some decades ago on attempts to distinguish between international and comparative librarianship. Although sound definitions for both fields were put forward and logic demands that they be clearly distinguished, the result was inconclusive, and this thread appears to have been abandoned. The practice of combining these two fields in textbooks and library science courses as "international and comparative library science" is pragmatic. Regardless of how the field is conceptualized, it can be expected to remain vital, since in a globalized world all fields of human endeavor have an increasingly significant international dimension. This applies *a fortiori* to librarianship, which serves the

conservation, development, and utilization of all human knowledge without regard to boundaries.

ACKNOWLEDGMENTS

I would like to thank Prof Theo Bothma and Serah Rademan of the Department of Information Science at the University of Pretoria and Jeannette C Jordan of the School of Information Studies, University of Wisconsin-Milwaukee for assistance in obtaining literature for me at a time when I was located far from a major academic library.

International Association of Sound and Audiovisual Archives (IASA)

Ilse Assmann

Radio Broadcast Facilities, SABC, Johannesburg, South Africa

Abstract

The International Association of Sound and Audiovisual Archives (IASA) was established in 1969 in Amsterdam to function as a forum for international cooperation between archives preserving recorded sound and audiovisual documents. This entry looks at the beginning years of IASA and its growth from nine founding members to an independent organization with a membership of more than 400 members, representing 64 countries.

BIRTH OF IASA

The International Association of Sound and Audiovisual Archives (IASA) was established in 1969 in Amsterdam to function as a forum for international cooperation between archives preserving recorded sound and audiovisual documents. During its 30-year anniversary celebrations, Rolf Schuursma, a founder member and former IASA President, divided its history into three periods, saying: "...Like every organization of this kind, beginning from scratch, IASA has gone through different stages, each with its own qualities and problems ...". Rolf (Schuursma, 1999) identified the stages as:

- *Getting acquainted*, when newly recruited members got to know one another and the membership was growing worldwide;
- *How did we do it*, during which time the membership studied the various ways of collecting, storing, cataloging, access, copyright, and technical matters, and during which time IASA became more professional in its management;
- *Widening the scope*, when IASA received international recognition and began to play a role in the international information field.

But a fourth stage can now be added: *digitization*; with IASA taking the lead by investigating new ways and setting standards to save sound and audiovisual collections, thereby preserving original qualities and enabling easy/easier access.

IASA was founded on August 22, 1969 after a letter of intent to establish a new international organization of sound archives was drafted the previous year and submitted to the *International Association of Music Libraries* (IAML). IASA's beginning was thus directly linked to the IAML.

IAML supported the floundering first few years when IASA lacked infrastructure and resources to host its own conferences. Harald Heckmann of IAML played an instrumental role in finding solutions that would eventually give IASA the independence it needed.

IAML had been officially founded in Paris in July 1951. Its Radio Library Commission which also had a Radio Sound Archive Subcommittee was primarily interested in music recordings. Before IASA came into existence, earlier attempts to unite sound archivists were made. The first initiative came from linguists who, in 1962, formed IALSA, (*International Association of Linguistic Sound Archives*) at a meeting in Amsterdam. Shortly thereafter, IALSA was absorbed by a newly founded organization, the *Fédération Internationale des Phonothèques* (FIP). The inactivity of FIP, however, led to the decline of the organization which practically faded away during the early 1970s.

Rolf Schuursma, at that time from the Archive at the Institute of History at Utrecht University in the Netherlands, remembers that it was Patrick Saul, the then director of the British Institute of Recorded Sound, who invited him to a meeting in Paris to participate as a representative of a spoken word recordings archive. The meeting took place in the *Département de la Musique* of the Bibliothèque Nationale in Paris on September 4, 1968. Seven members attended the meeting. They were IAML members Patrick Saul (Director of the British Institute of Recorded Sound), Vladimir Fedorov (Director of the Department and President of IAML), Dr. Kurt Dorfmueller (Bayerische Staatsbibliothek, München), Dr. Herbert Rosenberg (Director of the Nationaldiskotek in Copenhagen), Dr. Israel Adler (Director of the Jewish Music Research Centre at the Jewish National and University Library in Jerusalem), FIP president, Roger Décollogne (Director of the Phonothèque Nationale), and oral historian, Rolf

Schuursma, Rolf Schuursma from the Institute of History at the University of Utrecht, represented spoken word archives. Dr. Adler was the Chairperson. On September 5, a preliminary letter of intent was drafted to inform IAML of the decision by the meeting to establish a new international organization of sound archives. This letter was submitted by Dr. Adler to the IAML conference held in Washington DC and New York in 1969.

The first IASA meeting took place in Amsterdam at the *Institute of Theater Klank en Beeld (Institute for Theatre Sound and Image)* on August 18, 1969. The meeting was attended by Lou Hoefnagels (Director of the Theater Klank en Beeld), Rolf Schuursma, Patrick Saul, Donald L. Leavitt (Library of Congress), Philip Miller (Rodgers and Hammerstein Archives of Recorded Sound in New York), Dietrich Lotichius (Norddeutscher Rundfunk in Hamburg), Herbert Rosenberg, Claes Cnattingius (Swedish Radio), and Timothy Eckersley (BBC). This group of nine became known as the founding members of IASA. Earlier that year, in March, Rolf Schuursma and Lou Hoefnagels had already begun preparations for the first meeting. Don Leavitt presented the draft constitution for deliberation at the IAML conference in Amsterdam. A joint committee was formed between the Record Libraries' Commission and the newly founded IASA. In principle the roles were clear: IAML was interested only in music recordings and IASA in all recordings. But IAML also represented a branch of librarianship, whereas IASA was a response to the fact that sound recordings were more often held in an archival environment — a separate professional context at least equal to librarianship. IAML was not sufficiently hospitable to the technical challenges in the sound archives, which are most acute in the areas of unpublished recordings, held in archives, rather than published phonograms held by IAML member libraries. It would take a while before full agreement was achieved to avoid overlapping and even competing activities between IAML's Record Libraries' Commission and IASA.

The founding meeting took place on August 22, 1969 with 24 participants. The official name of the new organization was *International Association for Sound Archives*. The first Executive Board was made up by Don Leavitt (President), Patrick Saul (Vice-President), Claudie Marcel-Dubois (Vice-President), Rolf Schuursma (Secretary), and Claes Cnattingius (Treasurer). One of its primary tasks, together with the Record Libraries' Commission, was to prepare a *Directory of Sound Archives*, but this never happened. The concept was later replaced by an IASA *Directory of Member Archives*, first compiled by Ann Briegleb (Head of the Ethnomusicology Archive of the University of California at Los Angeles) in 1978, with an expanded update in 1982, and subsequently by the *Membership Directory*, which is still regularly published.

Initially IASA held joint annual conferences with IAML because of the lack of its own infrastructure and resources. During the Leipzig Conference in June 1970, a decision was taken that IASA should have its own periodical, and this led to the birth of the *Phonographic Bulletin*. The first issue was in A4 format with different shades of green for the cover and lettering and highlighting the IASA logo designed by Rob van der Elzen, a graphic designer with the Film Research Foundation. From Issue no. 16 onward the lettering on the cover was changed to black, and in 1977 the A4 format was replaced by the B5 format. In 1990, the IASA Board decided to publish a separate *Information Bulletin*, originally compiled by Vice-President Hans Bosma, in order to keep the membership more regularly informed about IASA-related activities. The publication was renamed *IASA Journal* in 1993 under the editorship of Grace Koch, with four *Information Bulletins* and two *IASA Journals* per annum being published instead of three *Phonographic Bulletins*. IASA now has its own Web site, and in 2006 the first *eBulletin* was published to keep members electronically informed. Currently, IASA publishes two *Information Bulletins*, two *eBulletins*, and two *Journals* per year, and maintains and updates the Web site regularly. IASA also operates a listserv to facilitate the exchange of information between members.

The joint 1971 IAML/IASA annual conference in St Gallen was a first for IASA in several respects. It was the first conference where IASA had a separate program (put together by Don Leavitt, Claes Cnattingius, and Rolf Schuursma), and the first issue of the *Phonographic Bulletin* (A4 format) (3 issues annually) was launched by Rolf Schuursma and Phita Stern (Utrecht).

By the time the 1972 joint IAML/IASA annual conference took place in Bologna, Italy, IASA had 40 institutional and 37 personal members. IASA's second Executive Board was elected with Timothy Eckersley (President), Claudie Marcel-Dubois, Herbert Rosenberg, and Ivàn Pethes (Vice-Presidents), Rolf Schuursma (Secretary), Claes Cnattingius (Treasurer), and Don Leavitt (Past-President).

Under the leadership of Timothy Eckersley, IASA further expanded its membership. It also became a fully recognized partner of the joint annual conference with IAML in London in 1973.

The election of the next IASA Executive Board in 1975 during the Montreal Conference was of particular significance. Two new members were elected that would help to take IASA decisively on a route to greater independence and recognition: Dietrich Schüller (Director of the Phonogrammarchiv in Vienna) and David Lance (Keeper of the Department of Sound Records of the Imperial War Museum in London). Dietrich Schüller was elected as President, and David Lance as Secretary, with Claudie Marcel-Dubois (Vice-President), Herbert Rosenberg (Vice-President), Rolf Schuursma (Vice-President), Léo

LaCLare (Treasurer), and Timothy Eckersley (Past-President).

The new Executive Board under the leadership of the young and dynamic Dietrich Schüller made dramatic changes to IASA. One of the first was to have midterm meetings to ensure better planning of annual conferences, and to discuss other issues and activities in which IASA had an interest.

The first midterm meeting was in April 1976 in the *Musée des Artes et Traditions Populaires*, Bois de Bologne, Paris, at which the Executive Board agreed to include the *Editor* on the Board. The first Editor was Rolf Schuursma, with Ann Briegleb replacing him as Vice-President. The Executive Board also decided to form committees to look after the specialized interests of the membership. The first committee was the Technical Committee with Dietrich Schüller as Chair, followed by the Copyright Committee under Robért Ternisien. David Lance initiated the formation of National Branches. The first national branches were established in Great Britain, the Netherlands, France and Australia. But several countries were already interested to unite audiovisual archives under one umbrella, something IASA as an association of sound archives did not cater for. Austria, therefore, never officially liaised with IASA, while the original Netherlands IASA branch broke away to form an independent Association of AudioVisual Archives. National branches also wanted to include non-IASA members, which had the potential to weaken IASA. In the early 1980s, following administrative difficulties with IASA International, the French and the Australian national branches broke away to form AFAS (Association française des archives sonores) and ASRA (Australasian Sound Recordings Association) as independent, but still IASA affiliated associations. This situation led to a drop in the number of IASA members, which was, however, compensated soon by the further growth. During the 1980s the IASA constitution was revised several times to reflect the changing nature of National Branches and independent organizations, known as Affiliated Organizations.

The year 1978 was nearly a watershed year for IASA.

During the 1978 mid-term meeting in Vienna, the constitution, which had originally followed the IAML model, was entirely renewed and adapted to the needs and realities of IASA. It was adopted at the Annual Conference in Lisbon. The basic structure is still in place today, with several adaptations to reflect the changing nature of the organization.

At the same conference, a new Joint IAML/IASA Committee on Music and Sound Archives was established to coordinate the activities of both organizations.

The fourth Executive Board was elected with Rolf Schuursma (President), Marie-France Calas (Vice-President), Tor Kummen (Vice-President), Ulf Scharlau (Treasurer),

Ann Briegleb (Editor), and Dietrich Schüller (Past-President). During the 1978 midterm meeting in Vienna, proposed changes to the Constitution were discussed: the election procedure needed to accommodate the entire membership as opposed to suggestions from the outgoing Executive Board, and the Council to be cancelled.

In 1983, Ulf Scharlau and Dietrich Lotichius were responsible for the formation of the Radio Sound Archives Committee for IASA while the Radio Sound Archives Subcommittee of IAML was suspended. In 1993, a name change was proposed at the Helsinki Conference, whereby the word “audiovisual” would be included in IASA to accommodate the breadth of audiovisual collections. The name change was officially accepted during the 1994 conference in Berlin-Bogensee, Germany, and IASA became known as *The International Association for Sound and Audiovisual Archives*.

In 1988, the time was ripe for IASA to hold its first solo conference in Vienna. It was attended by over 100 delegates, which proved the viability of IASA’s independence. During the following years, joint conferences with IAML were replaced by solo events or joint conferences with other audiovisual associations such as ARSC (Association for Recorded Sound Collections), FIAT (International Federation of Television Archives), SEAPAVAA (Southeast Asia-Pacific Audiovisual Archive Association) and ASRA (Australasian Sound Recordings Association).

YEARS OF GROWTH

The late 1980s and 1990s were a time of tremendous expansion of IASA, especially in the establishment of cooperation with UNESCO. Helen Harrison who was a Board member for over fifteen years, was instrumental in establishing the UNESCO Round Table, which later became the CCAAA (Co-ordinating Council of Audiovisual Archives Associations) under the leadership of Crispin Jewitt. The Technical Committee of IASA joined cooperation with Technical Committees of organisations such as FIAT, FIAF (International Federation of Film Archives), IFLA (International Federation of Library Associations) and ICA (International Council on Archives) and eventually formed the UNESCO TCC (Technical Coordination Committee) with George Boston of IASA as chairperson. This body organised the Joint Technical Symposia (JTS), which were and still are one of the most important professional meetings in audiovisual archiving. IASA also became closely involved in the UNESCO Memory of the World programme.

This period was also a fertile one for publications about audiovisual archive matters. Several ‘Special Publications’ were written, including *An Archive Approach* on

Oral History in 1978 and in 1983 Sound Archives: A Guide to their Establishment and Development by David Lance. For UNESCO Helen Harrison wrote the publication AV Archives: A Practical Reader which is still a valuable reference work and regularly accessed on the UNESCO website. This was the result of nearly five years work by a team from the Round Table and led by Gerry Gibson and Sven Allerstrand of IASA. *The Glossary* includes French, German and Spanish terms, as well as English terminology from both sides of the Atlantic. In 1978 Briegleb, Ann & Don Niles compiled the first Directory of Member Archives. The 2nd edition of the Directory of Member Archives was compiled in 1982 by Grace Koch.

With their excellent connections to non-governmental organizations, both Helen Harrison and Dietrich Schüller have boosted the Association's prestige by furthering its application to become a member of UNESCO. This success has enabled IASA to recruit new members from non-Western countries, i.e. countries in Asia, Africa, and South America. Since the end of the Cold War, IASA has gained many new members from the former socialist countries of Middle and Eastern Europe.

During the current decade IASA actively expanded its membership to Africa and South America with conferences held in 2003 in Pretoria, South Africa, and in México in 2006. A partnership between Dietrich Schüller and Albrecht Häfner in particular saw a series of very successful workshops across the world. The Board became truly representative of its international membership with members elected from India, Mexico, South Africa and Canada. IASA is currently respected for taking the lead by setting standards to digitally preserving sound and audiovisual collections.

IASA: THE ORGANIZATION

IASA has members from more than 60 countries, representing audiovisual archives and personal interests that are distinguished by their focus on particular subjects and areas. This includes archives for all sorts of musical recordings, historic, literary, folkloric and ethnological sound documents, theatre productions and oral history interviews, bioacoustics, environmental and medical sounds, linguistic and dialect recordings, as well as recordings for forensic purposes.

Every three years the IASA membership elects the Executive Board to oversee the business of the organization. Various committees, sections, and task forces are responsible for developing the work of IASA, and these serve as important information and discussion conduits in addition to dealing with specific areas of interest.

- The *Cataloging and Documentation Committee* looks after standards and rules, as well as with systems, automated or manual, for the documentation and cataloging of audiovisual media. The IASA Editorial Group, originally convened by Mary Miliano, compiled and edited the *IASA Cataloging Rules*, which is a manual for the description of sound recordings and related audiovisual media. An electronic version is available on the IASA Web site. It is also available in Spanish as *Reglas de Catalogación de IASA (2005 ed.)*.
- The *Discography Committee* deals with standards and recommended practices relating to collections of published recordings. The *National Discography* document provides guidelines on best practices for members who may have a responsibility for establishing national discographies in their countries, who intend to establish such a service, or who may be seeking funding.
- The *Technical Committee* devotes itself to all technical aspects of recording, storage, and reproduction, including new recordings, transfers, and storage technologies. Producing special publications that enable the audiovisual archive community to make educated decisions, is a main concern of the committee. The series "*Standards, Recommended Practices and Strategies*" includes
 - IASA-TC 03, *The Safeguarding of the Audio Heritage: Ethics, Principles and Preservation Strategy*, Version 3, December 2005, (Dietrich Schüller (Ed.)), which has been translated into German, French, Swedish, Italian, Spanish and Russian.
 - The IASA-TC 04, *Guidelines on the Production and Preservation of Digital Objects* (Kevin Bradley (Ed.)). The first edition (2004) is also available in Spanish and Italian. The revised, second edition, substantially enlarged and updated, was released in 2009.
- The *Training and Education Committee*, which had published the results in the *Phonographic Bulletin* of surveys of training for audiovisual archivists, typologies of sound archives, and existing job descriptions, became dormant in the mid-1990s. Recently it was revitalized under the leadership of Vice-President Pio Pelizzari and concerns itself with audiovisual training and education in the educational context, bibliographies of training and education-related publications, as well as concentrated actions in gaining multifunctional training and education material.
- The *National Archives Section* is where members meet to consider issues facing national archives, e.g., acquisition policies, legal deposit, and the management of large collections. Policy guidelines for the *legal*

deposit of sound recordings have been published and are available on the Web site.

- The *Radio Sound Archives Section* handles the special responsibilities of audiovisual archives in broadcasting companies.
- The *Research Archives Section* concerns itself with special issues relating to audiovisual archives whose holdings include collections of recordings originally made for research purposes.

IASA's Technical Committee follows closely the progress of technology, and the association's members can call upon a pool of expertise for help and advice on all technical problems faced by AV archives including digitization and problems arising from the use of computer storage systems for heritage collections. As such IASA has published the following publications in addition to those already mentioned:

- Treatment and restoration of historical audio recordings.
- Standards for International Tape Exchange (1978).
- Role of the Compact Disc (1982).
- Automation of Archive Systems (1989).
- Analogue and Digital Technologies for Restoration and Long-term protection of endangered recorded sound collections.

IASA "Task Forces" report on specific topics of interest to the membership such as selection criteria and endangered carriers. These and other reports will be made available on the IASA Web site as they are completed. In this regard the IASA published the Task Force findings to establish *Selection Criteria of Analogue and Digital Audio Contents for Transfer to Data Formats for Preservation Purpose* (Majella Breen, Gila Flam et al. (Ed.)).

IASA enjoys international cooperation with organizations such as UNESCO and has partnered with organizations such as AFAS, ARSC, IFLA, FIAT, and FIAF. IASA is also a founding member of the CCAAA.

Current membership: 411 members representing 64 countries

- Institutions: 224
- Individual: 184
- Sustaining: 3

Honorary members: The first honorary member was Tim Eckersley in 1980. Current honorary members are Claes M. Cnattingius (Sweden), Gerald Gibson (U.S.A.), Carlo Marinelli (Italy), and R.L. Schuursma (the Netherlands).

APPENDIX

Table A.1 List of IASA Presidents and terms served.

	Term	Name	Institution
1	1969–1972	Donald Leavitt	Library of Congress, United States
2	1972–1975	Timothy Eckersley	BBC, United Kingdom
3	1975–1978	Dietrich Schüller	Phonogrammarchiv, Austrian Academy of Sciences, Austria
4	1978–1981	Rolf L. Schuursma	Foundation Film and Science, the Netherlands
5	1981–1984	David G. Lance	Imperial War Museum, United Kingdom
6	1984–1987	Ulf Scharlau	Süddeutscher Rundfunk, Germany
7	1987–1990	Helen P. Harrison	Open University, United Kingdom
8	1990–1993	Gerald D. Gibson	Library of Congress, United States
9	1993–1996	James McCarthy	National Film and Sound Archives, Australia
10	1996–1999	Sven Allerstrand	ALB, Sweden
11	1999–2002	Crispin Jewitt	British Library National Sound Archive, United Kingdom
12	2002–2005	Kurt Deggeller	MEMORIAV, Switzerland
13	2005–2008	Richard Green	National Library of Canada, Canada
14	2008–	Kevin Bradley	National Library of Australia, Australia

International Association of Technological University Libraries (IATUL)

Nancy Fjällbrant

Chalmers University of Technology Library, International Association of Technological University Libraries, Gothenberg, Sweden

Alice Trussell

Hale Library, Kansas State University, Manhattan, Kansas, U.S.A.

Abstract

The International Association of Technological University Libraries (IATUL) was founded in Düsseldorf, Germany, in May 1955, as an international forum for the exchange of ideas relevant to librarianship in technological universities throughout the world. The IATUL is a voluntary international nongovernmental organization of a group of libraries, represented by their library directors or senior managers, who have responsibility for information services and resources management. Many of the members of IATUL provide services, not only to the teaching and research staff and students of their own university but also to industrial organizations and national research institutions, in their respective countries. The main objective of IATUL is to provide a forum where library directors and senior managers can meet to exchange views on matters of current significance and to provide an opportunity for them to develop a collaborative approach to solving problems. The IATUL is an excellent example of the development of an effective informal international network between libraries of similar type, with a common high level of professional expertise and offering a similar range of services to their users. The IATUL also welcomes into membership organizations that supply services to university libraries, if they wish to be identified with the association's activities. This entry will examine the historical development, membership, organizational structure, activities, and publications of IATUL.

INTRODUCTION

The International Association of Technological University Libraries (IATUL) was founded in Düsseldorf, Germany, in May 1955, as an international forum for the exchange of ideas relevant to librarianship in technological universities throughout the world. The IATUL is a voluntary international nongovernmental organization of a group of libraries, represented by their library directors or senior managers, who have responsibility for information services and resources management. Many of the members of IATUL provide services, not only to the teaching and research staff and students of their own university but also to industrial organizations and national research institutions, in their respective countries. The main objective of IATUL is to provide a forum where library directors and senior managers can meet to exchange views on matters of current significance and to provide an opportunity for them to develop a collaborative approach to solving problems. The IATUL is an excellent example of the development of an effective informal international network between libraries of similar type, with a common high level of professional expertise and offering a similar range of services to their users. The IATUL also welcomes into membership organizations that supply services to university libraries, if they wish to be identified with the association's activities.

HISTORY AND DEVELOPMENT OF IATUL

Dr. E. Hemlin from Chalmers University of Technology, Sweden was the founder of IATUL and also its first president, and, in this capacity, he did much to develop the association. In September 1955, IATUL was recognized as a subsection of the International Library Association's division of the International Federation of Library Associations and Institutions (IFLA). This division no longer exists, and IATUL, as an International Library Association member, now works in association with the IFLA Section of Science and Technology Libraries. In 1990, IATUL was formally affiliated with UNESCO. This affiliation operates now through IFLA. Since 1999, IATUL is also a member of the International Council for Scientific and Technical Information.^[1–3]

In the early years, many of the members of IATUL came from Europe, where there were a number of well-established institutions for technological education. The eighteenth century had seen the founding of some of the earliest "schools" of this type in France, Germany, and Hungary. The first half of the nineteenth century was a period of considerable economic and social growth and development. This period saw the increasing use of steam power for industry, the rapid change from local craft

production to factory-based industries, and considerable improvements in communications. These changes led to an increased need for the provision of technical education and training, resulting in the founding of “trades and craft schools,” and polytechnic institutions throughout Europe. Similar institutions were founded in the United States.^[4] The early members of IATUL came mostly from European universities of technology and from some American institutions. During the last 25 years, there has been a steady growth in IATUL members coming from all parts of the world, resulting in a truly international organization.

At the 16th IATUL Conference, which was held at the University of Twente in the Netherlands in 1995, IATUL celebrated its first 40 years with a special session on the history of the organization. Several papers given at this session by previous board members provide interesting glimpses of the history of IATUL from a variety of angles.^[5–8] The 50th anniversary was celebrated at the 26th IATUL Conference, which was held at the University of Laval in 2005. An extensive display of historic photographs was on display, and the speakers at the conference banquet provided a warm reflection on half a century of service.

MEMBERSHIP

Ordinary and associate membership of IATUL is open to the libraries of universities and other higher educational institutions that offer programs of science and technology. Applications for membership of IATUL shall be addressed to the Secretary of the Association. In addition to academic institutional membership, there are two other types of membership. These are the categories of membership:^[9]

Ordinary membership—available to libraries/information services whose institutions offer masters or doctoral degrees in engineering, science, or technology;

Associate Membership—available, subject to confirmation by the Board, to libraries/information services interested in supporting the aims and objectives of IATUL

Honorary Membership—which the Board may confer upon individuals who have served the Association, or international librarianship, with particular distinction; and

Sustaining Membership—available, subject to confirmation by the Board, to commercial organizations interested in supporting the aims and objectives of IATUL

In an effort to recruit more members from countries and continents outside of Europe, a graduated membership fee structure was adopted at the general meeting in 2005. The new fee structure was based on the UNESCO Scale of Assessments. Libraries in those countries whose current UNESCO assessment is at 0.251 or greater pay the

standard fee. Those libraries in countries whose UNESCO assessment is at 0.250 or below pay a fee of 50% of the standard membership rate.^[10] In 2007, President Maria Heijne reported that there were 241 member libraries from 46 countries.^[11] The IATUL is small enough to allow individual members to develop a close relationship, yet widespread enough to cover the interests of libraries operating in virtually all modern social, economic, and political situations.

ORGANIZATION AND ACTIVITIES

The association is governed by a Board of Directors consisting of the President, First Vice-President, Second Vice-President, Secretary, Treasurer, Immediate Past President, and at least three board members elected by member libraries.^[9] The board meets at least two times each year. Beginning in 2005, the board organizes a regional seminar in conjunction with the fall board meeting. The goals of hosting a regional seminar are to “interact with representatives of local libraries, to share information about developments for technological university libraries, and to create interest for the activities of IATUL.”^[12] The current president of IATUL is Maria Heijne, University Librarian at the Delft Institute of Technology. The IATUL brings its members together by means of meetings, an e-mail list for members, and a Web site. The meetings include conferences, seminars, and regional gatherings. The conferences started as triennial meetings, which then became biennial, and finally, in 1997, annual conferences. During the period of biennial conferences, seminars were held during the year when there was no conference.

Recent conferences:

- The 28th IATUL Conference was held at the Royal Institute of Technology, Stockholm, Sweden in 2007 with the theme *Global Access to Science*.
- The 27th IATUL Conference was held at the Faculdade de Engenharia, Universidade do Porto, Portugal in 2006 with the theme *Embedding Libraries in Learning and Research*.
- The 26th IATUL Conference was held at the Université Laval Library, Québec City, Canada in 2005 with the theme of *Information and Innovation*.
- The 25th IATUL Conference was held at the Library of Krakow University of Technology in Krakow Poland in 2004 on the theme of *Library Management in Changing Environment*.
- The 24th IATUL Conference was held at the Middle Eastern Technical University in Ankara, Turkey in 2003 on the theme of *Libraries and Education in the Networked Information Environment*.
- The 30th IATUL Conference was held at the Katholieke Universiteit Leuven Belgium in 2009 with the theme of *Just for you: Quality through innovation*.

- The 29th IATUL Conference was held at the Auckland University of Technology, Auckland New Zealand in 2008 with the theme of *Digital Discovery: Strategies and Solutions*.

Conferences immediately prior to these most current ones were held in Greece, Norway, Australia, the United States, and South Africa. The scope of the conference themes and venues illustrate the world-wide impact of IATUL. Future plans for IATUL will take the annual conferences to Purdue University in the United States in 2010 and to Warsaw University of Technology in Poland in 2011.

PUBLICATIONS

The first IATUL publications were a series of irregular reprints and publications from 1956 (Number 1) to 1967 (Number 25).^[13] The first regular publications of IATUL were the *Newsletters* (January 1963–November 1965) with about 20 more extensive contributions and innumerable brief reports about the activities of the members. In 1965, the journal *IATUL Proceedings* started publication. Publication started at Delft University of Technology in the Netherlands and was transferred first to Loughborough University of Technology in the United Kingdom during the years 1968–1973, and then from 1974 till 1986 to Chalmers University of Technology, Gothenburg, Sweden.^[14]

From 1987 to 1991, the *IATUL Proceedings* and the *IATUL Conference Proceedings* were merged to form the *IATUL Quarterly* (Volumes 1–5) published by Oxford University Press. Owing to the high costs of publishing the *IATUL Quarterly*, it was decided to cease publication in 1991 and instead to publish the *IATUL News* as a quarterly newsletter, with the aim of providing a timely flow of information to members, together with the annual *IATUL Proceedings (New Series)*, which contains a selection of the papers presented at the IATUL Conferences and Seminars.

From 1996 onward, papers from *IATUL Proceedings* are available on the IATUL Web site at <http://www.iatul.org>. From 1997 to 2006, the *IATUL Proceedings (New Series)* is also distributed in a CD-ROM version; prior to 1997, a print version was produced. For a description of the *IATUL Proceedings* see the article published in 1996 by Elin Törnudd, former president of IATUL—*IATUL as a Mirror of Library Developments Since 1966 as Documented in IATUL Proceedings*.^[6] The *IATUL News*, Editor Nancy Fjällbrant, was published at Chalmers University of Technology from 1992 onward, in two forms: as a print publication from 1992 to 2000, with a parallel Web version available beginning in 1994. At the 2000 General Assembly of IATUL in Brisbane, it was decided to end the printed version of the *IATUL News* at the end of 2000. Distribution of IATUL News moved to mailing lists with archived issues maintained on the organizational Web site. This transition brings about the realization of the IATUL Electronic Publishing Plan that was launched in 1997—

with the aim of publishing all the IATUL publications in electronic form.

CONCLUSION

Although IATUL began as a European centric organization of technological university library managers, the scope of service and participating membership has expanded far beyond the geographical distribution of the original members. The IATUL continues to build membership and service to the engineering and technology library community around the world. The IATUL has recognized that due to variations in university organizational differences, participation by university libraries offering a wide scope of disciplines including engineering and technology needs to be cultivated. This organizational difference is most noticeably present in North America, where participation by universities is greatly encouraged. The forum provided by IATUL for the exchange of ideas relevant to engineering and technological librarianship continues to help enable the library community to meet the challenges of the twenty-first century information needs.

International Communication Association (ICA)

Ronald E. Rice

Department of Communication, University of California–Santa Barbara, Santa Barbara, California, U.S.A.

Abstract

The International Communication Association (ICA, 1500 21st Street, NW, Washington, D.C. 20036, Tel.: 202-955-1444; Fax: 202-955-1448, E-mail: icahdq@icahdq.org; <http://www.icahdq.org>) is an academic association for scholars interested in the study, teaching, and application of all aspects of human and mediated communication. ICA is an international association with over 4500 members. This entry summarizes its history, governance and administration, past presidents, divisions and interest groups, membership, annual conferences, fellows, awards, links with other communication associations, publications, impact factors and local citation environments of ICA, and references. Much of this material comes from ICA's website, with permission.

INTRODUCTION

ICA is an academic association for scholars interested in the study, teaching, and application of all aspects of human and mediated communication. ICA is an international association with over 4700 members from nearly 90 countries. Since 2003, ICA has been officially associated with the United Nations as a nongovernmental association. The overall purposes of the association are to advance the scholarly study of human communication and to facilitate the implementation of such study so as to be of maximum benefit to humankind. The association seeks to achieve this purpose by 1) encouraging the systematic study of theories, processes, and skills of human communication; and 2) facilitating the dissemination of research through an organizational structure responsive to communication study areas, a program of organizational affiliates, regular sponsorship of international meetings, and a commitment to a program of scholarly publication. This entry summarizes its history, governance, presidents, divisions and interest groups, membership, annual conferences, awards, and journals.

THE EARLY DAYS

The National Society for the Study of Communication (NSSC) was founded in 1950, led by such individuals as Elwood Murray, Paul Bagwell, Ralph Nichols, and Wesley Wiksell, from its parent organization the Speech Association of American (now the National Communication Association) partially to support and encourage the study of communication as a research topic instead of as primarily rhetoric. The first issue of the *Journal of Communication* appeared in 1951. In order to reflect the increasingly more diverse makeup of the society, four

initial divisions were formed in 1968: information systems, interpersonal communication, mass communication, and organizational communication. The NSSC changed its name in 1969 to the International Communication Association. During this period, membership rose from 900 members in 1967 to more than 2000 members in 1971. The first annual convention outside North America was held in West Berlin in 1977. (For a detailed history of the first quarter century of the International Communication Association, see Weaver.^[1] For more detail and references, see http://www.icahdq.org/about_ica/history.asp.)

GOVERNANCE AND ADMINISTRATION

The ICA Board of Directors includes an Executive Committee (the president, president-elect, immediate past-president, and past-president, the president-select-elect, and, ex-officio, the chair of the financial committee—who is the past-past president—and ICA's executive director), the chairs of the divisions and interest groups, two student members, and board members at large representing Africa-Oceania, non-U.S. Americas, East Asia, West Asia, and Europe. This regional (based on United Nations criteria) representation was implemented in 2000 to reflect the increasingly international focus of ICA. Standing committees of ICA include membership and internationalization, student affairs, finance, publications, nominating, and sustainability, as well as committees for each award. The headquarters relocated from Austin, Texas, to Washington, D.C. in 2001, and purchased its own office building in 2006. The full-time staff includes an executive director, a member services director, a publications manager, a communication director, an executive assistant, and a member services associate.

PRESIDENTS

In the year that ICA presidents are elected, they are responsible for determining the theme of the following year's conference. In that following year, the "president-elect" is responsible, working with the executive director, staff, and the executive committee, for selecting a conference theme chair and organizing that year's annual conference, responding to a constant flow of requests, proposals, and administrative matters, and representing ICA. In the following year, the "president" presides over board meetings and that year's annual conference, reconstitutes all the committees, represents ICA, attends to policy and other matters that come before ICA, and presents the presidential address. Table 1 lists the ICA presidents.

DIVISIONS AND INTEREST GROUPS

ICA's principal areas of concern are represented by its divisions and interest groups. These currently include 20 divisions (each maintains a membership of at least 10% of all ICA members) and five interest groups (newly founded sections with at least 20 members). Table 2 lists the divisions and interest groups. Two network analyses of the joint memberships and paper titles in ICA's division and interest groups revealed three underlying dimensions of the groups: mediated/interpersonal, humanistic/scientific, and theoretical/applied.^[2,3]

MEMBERSHIP

ICA's membership hovered around 500 until 1967, to 2000 by 1970, to 3000 after 2001, and by June 2014 included 4700. Some two-thirds are teaching and conducting research in colleges, universities, and schools around the world, while others work in the media, communication technology, business law, medicine, government, and other professions.

As part of ICA's continuing emphasis on increasing internationalization, about half of its committee members and about half of the board of directors are members of non-U.S. universities. Of the 80 countries represented in ICA, the greatest percentages of ICA membership include, at 58% the United States; from 8% to 2%: Germany, the United Kingdom, the Netherlands, Canada, and Australia; and from 1.5% to 1%: Switzerland, Japan, Republic of Korea, Israel, Belgium, Hong Kong, Sweden, and Singapore.

ICA has a triple-tiered dues structure following the United Nations model for A, B, and C countries. Residents of B-tier countries pay 75% of the A-tier price and residents of C-tier countries pay 50% of the A-tier price. These differing fee levels were instituted in 2002 to

Table 2 ICA divisions and interest groups (IG).

<i>Children, adolescents, and the media:</i>	Focuses on the production, content, uses, and reception of both print and electronic media. It strives to be a fruitful intellectual forum for academics from all over the world who study the role of media in the lives of children and young people. CAM's orientation is interdisciplinary and multimethodological.
<i>Communication and technology:</i>	Focuses on information and communication technology in relation to processes of human communication. Specifically it addresses new media, social media, human–computer interaction, computer-mediated communication, mobile communication, “big data,” crowdsourcing, and other technologically mediated social interaction and networking in all contexts and levels of analysis. CAT is not about technology per se, but rather about the interaction with social and personal entities at the micro, meso, and macro level.
<i>Communication history:</i>	Promotes theory, research, and professional education in the history of communication. the notion of “communication history,” in this interest group, pulls together three major areas of research: the history of communication including media history, the history of the idea of communication, and the history of the field of communication.
<i>Communication law and policy:</i>	Is interested in research and analysis of law, regulation, and policy that deals with information, communication, and culture. Defining policy broadly, the division includes within its purview: principles that should or do underlie law and regulation, proposals for new law and regulation, and the programs and institutions through which policy is implemented.
<i>Environmental communication:</i>	Advances research on the interplay of the environment with any level of communication and in any setting. Specific foci include health, risk, and science communication. Also helps members integrate sustainability issues into their teaching and research.
<i>Ethnicity and race:</i>	Is concerned with methodological approaches and research that apply, extend, or develop communication theory and analysis through an examination of race and ethnicity within local, international, and transnational contexts. Advocates for the improved status, representation, and opportunities for underrepresented scholars in communication.
<i>Feminist scholarship:</i>	Is interested in exploring the relationship of gender and communication, both mediated and nonmediated, within a context of feminist theories, methodologies, and practices. Areas include feminist teaching; international commonalities and differences by race, class, and gender; women's alternative media; and feminist cultural studies.
<i>Game studies (IG):</i>	The study of games and the game experience offers opportunities for the study of human communication that involve multidisciplinary approaches that merge the disciplines of conventional communication studies and research, arts and visual design, cognitive studies, computer sciences, cultural studies, engineering social sciences, health sciences, and information design.
<i>Global communication and social change:</i>	Encourages and debates research on issues of production, distribution, content, and reception of communications media at global, “glocal,” transnational, transcultural, international, and regional levels.
<i>Health communication:</i>	Is primarily concerned with the role of communication theory, research, and practice in health promotion and health care. Areas of research include provider–patient interaction, social support networks, health information systems, medical ethics, health policy, and health promotion.
<i>Information systems:</i>	Is concerned with information, language, and cognitive systems. Its central goal is promoting the development of general theories of complex systems and quantitative methodologies for communication research in a variety of domains.
<i>Instructional and developmental communication:</i>	Is concerned with both communication related to any learning environment and communication that transpires across the life span. Its dual goals include promoting the study of communication variables and theory in the instructional process and promoting the study of communication as a developmental phenomenon across the complete life span.
<i>Intercultural communication:</i>	Is primarily concerned with theory and practice of communication between and among different cultures of the world; with comparisons of different communication systems in different cultural, national, or ethnic groups; with other aspects of international communication; and with the relationship between communication and national development.
<i>Intergroup communication (IG):</i>	Focuses on the ways in which communication within and between groups affects social relations. Intergroup encounters occur when social, rather than personal, identity forms the basis for communication. Intergroup communication is often characterized by power inequality, bias, competition, or conflict. Some relevant topics would include prejudice and discrimination, social identity processes, language survival and death, social influence, leadership, communicative shifts and concomitant effects on relationships, computer-mediated communication, linguistic biases, power, terrorism, collaboration, and altruism.

(Continued)

Table 2 ICA divisions and interest groups (IG). (Continued)

<i>Interpersonal communication:</i>	Emphasizes the study of communication processes between people in a variety of settings, including friendship formation, influence, relationship development, small group processes, and family relations, through face-to-face and mediated communication.
<i>Journalism studies:</i>	Is concerned with journalism theory, journalism research, and professional education in journalism, across temporal and geographic contexts. The division seeks to facilitate empirical research and to bring more coherence to research paradigms.
<i>Language and social interaction:</i>	Is concerned with exploring details of human discourse and human interaction. The division sponsors research in language theory, linguistics, pragmatics, semiotics, sociolinguistics, ethnography of speaking, conversation analysis, and related approaches to human social interaction. The primary focus is in interpersonal and group settings, through face-to-face or mediated communication.
<i>Lesbian, gay, bisexual, transgender, and queer studies (IG):</i>	Is concerned with the analysis and critique of sexual systems, discourses, and representations, particularly those which animate, inform, and impinge upon the lives of lesbian, gay, bisexual, and transgender people. Such systems and discourses occur in institutional, community, domestic and intimate contexts, are closely connected to other social and cultural practices (such as nationalism, education or popular entertainment), and play a critical role in the formation and communication of individual and group identity.
<i>Mass communication:</i>	Is primarily concerned with the differential impact of messages transmitted by various mass media, including international exchanges through mass media. Its members develop theory, examine the processes and effects of mass communication, and develop and evaluate policy relevant to mass communication.
<i>Media industry studies (IG):</i>	Promotes research and teaching practice on the history, organization, structure, economics, management, production processes, and cultural forms, and the societal impact of media industries from a variety of theoretical, empirical, and cultural perspectives. Among other things, our members study the relationship between government and industry, the intersection of audience and industry, audiences as consumers, the business of media, production and creative labor, ownership structure, and content diversity from a range of micro and macro-levels
<i>Mobile communication (IG):</i>	Studies the phenomenon of mobility in communication—the intersection of mobility, technology, and culture in human communication. Members apply a wide array of perspectives from historical perspectives to studies on future media innovations, from ethnographic to quantitative empirical approaches, from journalism studies to media effects research. The common ground is state of the art theorizing on mobile communication as well as the discussion of adequate methodology to do so.
<i>Organizational communication:</i>	Seeks to expand our understanding of the processes, prospects, and challenges of communicating and organizing in a global society. Its scholarship articulates concepts and theories to better understand these processes, develops the tools needed to investigate them, and helps to implement the social practices to improve them.
<i>Philosophy, theory, and critique:</i>	Is broadly concerned with theoretical, analytical, and political issues that cut across the various boundaries within the study of communication and its intersections with other modes of studying human interaction.
<i>Political communication:</i>	Is concerned with the interplay of communication and politics, including the transactions that occur among citizens, between citizens and their governments, and among officials within governments.
<i>Popular communication:</i>	Is concerned with providing a forum for scholarly investigation, analysis, and dialogue among communication researchers interested in a wide variety of communication symbols, forms, phenomena, and strategic systems of symbols within the context of contemporary popular culture.
<i>Public relations:</i>	Is concerned with the theory and practice of communication between organizations and specified publics. Research interests include target group analysis, internal/external communication integration, systems analysis, and channel effectiveness.
<i>Public diplomacy (IG):</i>	
<i>Sports communication (IG):</i>	Intends to understand human and mediated communication processes and effects within sports contexts.
<i>Visual communication studies:</i>	Seeks to enhance the understanding of the visual in all its forms—moving and still images and displays in television, video and film, art and design, and print and digital media. Research areas include creation, processing, function, meaning, and critical consequences of visual representation.

Table 3 Membership in ICA divisions and interest groups.

Division or interest group	Percent of all memberships
Children, adolescents, and the media	2.9
Communication and technology	9.8
Communication history	2.7
Communication law and policy	2.9
Environmental communication	2.2
Ethnicity and race in communication	2.3
Feminist scholarship	2.5
Game studies	2.2
Gay, lesbian, bisexual, and transgender studies (IG)	1.2
Global communication & social change	4.5
Health communication	5.6
Information systems	3.4
Instructional/developmental communication	1.9
Intercultural communication	4.3
Intergroup communication (IG)	1.6
Interpersonal communication	3.9
Journalism studies	6.0
Language and social interaction	2.3
Mass communication	10.2
Organizational communication	5.5
Philosophy, theory, and critique	4.2
Political communication	7.6
Popular communication	3.8
Public relations	4.2
Sports communication (IG)	0.0
Visual communication studies	2.5
Total	10785

Note: There are 4500 unique members, and one division or interest group is provided free with membership, but members typically belong to multiple divisions or interest groups. So, the total is the overall total of group registrations (including multiple groups for a person), and the percentage is based on that.

continue the increased emphasis on international representation. Membership categories for individuals include regular, employment exception, student, emeritus, life, and sustaining. Membership categories for groups include family, institutional, and association. Members may join one division/interest group as part of regular dues and may add additional divisions/interest groups for a few dollars.

Table 3 presents the percentage of memberships for each division and interest group. Mass communication has the greatest percentage of memberships as of 2014.

The primary benefits to members of ICA include opportunities to network with colleagues who share teaching and research interests worldwide; access to membership in the divisions and interest groups and their related websites; attendance at annual conferences at member rates with discounted air/hotel/car rates; print or online subscriptions to five professional journals; and access to the annual yearbook at a members-only discount. Other book discounts include several series: Blackwell's *Communication in the Public Interest* and *The International Encyclopedia of*

Communication, Routledge's *ICA-LEA Handbook Series*, and Hampton Press's *ICA Theme Series* (highlighting the primary theme of each year's conference theme sessions), as well as discounted membership in the Communication Institute for Online Scholarship (<http://www.cios.org>). Finally, ICA's website contains the latest information and allows for online registration for conferences and membership renewals; provides the latest information, online access to ICA journals, and the ICA membership directory; and provides access to the ICA online newsletter, published 10 times per year, which includes job listings, association and member news, ICA officer columns, and calls for papers.

ANNUAL CONFERENCES

The ICA annual conference is generally held each year at the end of May when in North America and in June or July when outside of North America. About 1500–2000 scholars come together at this event to learn about the latest research, socialize with colleagues, visit the city, and learn about job opportunities. Submitted papers undergo a double-blind peer review process; in 2005 a record number of 2300 papers were submitted (New York); in 2006, 2000 were submitted (Dresden). Another change to expand the international identity and presence of Caws to increase the frequency of annual conferences held outside of North America from every 4 years to every 3 years, beginning in 2010. Non-U.S. conferences include Berlin (1977), Acapulco (1980), Montreal (1987), Dublin (1990), Sydney (1994), Montreal (1997), Jerusalem (1998), Acapulco (2000), Seoul (2002), Dresden (2006), Montreal (2008), Singapore (2010), London (2013), Fukuoka Japan (2016), and Prague (2018).

FELLOWS

ICA annually recognizes distinguished scholarly contributions to the broad field of communication, as well as service to ICA and other public institutions through fellow status. Currently, there are over 100 Fellows. Meyen^[4] published an insightful "collective biography" based on interviews with 57 Fellows. To some extent, fellows are representatives of dominant paradigms, provide role models, are agents in field's decision-making, and influence perceptions and expectations. They are influenced by the geography of the field's founders and universities, by family background and academic socialization, a shift from the early emphasis on journalism to a more social science perspective, a commitment to field of communication and its symbolic capital, and their interest in service and mentoring and working with graduate students.

AWARDS

ICA presents eight major awards at the annual conference to recognize significant research in and contributions to the field. ICA divisions and interest groups also offer their own awards.

Steven H. Chaffee Career Achievement Award

The award honors a scholar (or small group of collaborating scholars) for sustained work on a communication research problem over an extended period. The selection committee favors research that is original, asks conceptually rich questions, and offers empirically sound evidence. The research must have comprised multiple projects and publications and generated second-generation work among students and other scholars. Rather than recognizing general productivity in the field or contributions to ICA, the award acknowledges sustained and coherent work on a well-focused communication problem central to the communication discipline. Most recipients are members of the discipline and belong to ICA, but other scholars are eligible, regardless of current membership or department affiliation. The winner presents research at the following year's ICA conference.

James W. Carey Urban Communication Grant

This annual prize supports communication research that enhances urban social interaction and civic engagement in an age of global communication. It encourages applied research on the role of city and community at a time when communication technology alters the parameters of the urban landscape. The award is for proposals that feature innovation and creative approaches to reconciling the growing gap between tradition and modernity as suburban sprawl threatens the very nature of urban traditions. This award facilitates research in progress or in the planning stages. It gives priority to projects that study places where traditional modes of communication are being juxtaposed with the new, including the adoption of changes that may have a radical impact. Proposals from developing nations are encouraged.

Outstanding Book Award

The award honors a book published in the previous two calendar years (between January 1 and December 31). The selection committee judges each nominated book on several criteria including the importance of the problem it addresses in the fields represented in ICA and to communication studies as a whole, the quality of writing and argument, and the strength of evidence it presents. The committee will consider all the available book reviews, the reputation of the publisher, and any other submitted evidence regarding the book's quality from independent sources, along with

nominating letters and their own assessment of the nominated books. Most award-winning books address a scholarly audience, but books aimed at a general readership but satisfying the criteria for the prize are also eligible—edited books are not eligible.

Applied Research Award

The Applied Research Award honors a scholar or group of scholars who has or have produced a systematic and outstanding body of research that addresses a significant communication problem of relevance to a public representing one or more groups of stakeholders relevant to a division (s) or interest group(s) of ICA. Individual or collaborative applied research programs that include community engagement, group and organizational interventions, or advocacy and/or political policy work at the local, national, international, and/or global levels are all appropriate candidates for this award. Evidence for quality and public importance can come from conventional publications but also from such materials as technical reports, news media coverage, and testimonials from those making use of the research or those it has affected.

Outstanding Article Award

The award honors an article published in a refereed journal during the previous two calendar years (between January 1 and December 31). Theoretical articles and empirical articles are eligible, as are review articles that effectively redefine a problem. Selection criteria include coherence of argument, quality of conceptual development, and effective use of evidence. The selection committee prefers articles that promise to be influential over time, within particular field of communication and also across fields.

Young Scholar Award

The award honors a scholar no more than 7 years past receipt of the Ph.D. for a body of work that has contributed to knowledge of the field of communication and shows promise for continued development. The selection committee judges the contribution and promise of young scholars based on the strength of published work, including its conceptual foundation and argumentative clarity, on the scholar's productivity at a given career stage, on the rigor of the research produced so far, and on the promise of existing work serving as a springboard for continuing scholarship.

B. Aubrey Fisher Mentorship Award

Initiated in 1988 following the death of its namesake, this award honors outstanding scholars, teachers, and advisors who serve as role models in those capacities and

who have had a major impact on the field of communication. Most importantly, recipients of this award have influenced the discipline through their former students, who themselves are important figures in the communication discipline.

ICA Fellows Book Award

Open to all ICA members, this award recognizes those books that have made a substantial contribution to the scholarship of the communication field as well as the broader rubric of the social sciences and have stood some test of time.

LINKS WITH OTHER COMMUNICATION ASSOCIATIONS

ICA fosters collaboration with other communication associations, including co-sponsoring conferences, and providing affiliate organizational status. Current relations include Asociacion de Comunicacion Politica; Bangladesh Center for Communication Programs; BBC Media Action; Binational Association of Schools of Comm of the Californias; Brazilian Society of Interdisciplinary Studies in Communication; Chinese Communication Association; Deutsche Gesellschaft fur Publizistik-und Kommunikationswissenschaft; Institute of Digital Media and Child Development, Inc.; International Association of Language & Social Psychology; International Association for Media and Communication Research; International Environmental Communication Association; Korean American Communication Association; Media Ecology Association; National Association of Mass Media Researchers; Polish Communication Association; and the Russian Communication Association.

PUBLICATIONS

The annual *Communication Yearbook* (begun in 1977) publishes state-of-the-art literature reviews and articles providing comprehensive syntheses of literature. *Communication Theory* (1991) publishes research articles, theoretical essays, and reviews on topics of broad theoretical interest from across the range of communication studies. *Human Communication Research* (1973) publishes the

best empirical research examining communication processes and effects. The *Journal of Communication* (1969) is a general forum for communication scholarship and publishes articles and book reviews examining a broad range of issues in communication theory and research. The *Journal of Computer-Mediated Communication* (acquired in 2003) is a Web-based journal that publishes scholarship on computer-mediated communication. ICA added a fifth journal, *Communication, Culture & Critique*, beginning 2008; it is an international forum for critical, feminist interpretive, and qualitative research examining the role of communication from a cultural and historical perspective. Beginning in January 2007, the abstracts of the articles of each of the journals are also provided through the publisher's databases, translated into Spanish, Korean, French, Chinese, and German.

IMPACT FACTORS AND LOCAL CITATION ENVIRONMENTS OF ICA JOURNALS

The underlying citations to and from journals, as reported in ISI's Journal Citation Report, are the basis for computing each journal's citation impact factor. Citation Impact Ratings are the ratio of number of citations received to articles in that journal, divided by number of articles published in that journal 2 years prior. Table 4 provides the 2011, 2013, and 2013 5-year ISI journal citation impact factors for the ICA journals.

The article citation data are also the basis for identifying clusters of shared concepts, journals, and authors—one widely used form of bibliometrics, or citation analysis. Leydesdorff^[5] developed a reasonable way to extract what he calls “journal-citation environments” from the otherwise unwieldy matrix of possible citation relations (with over 1700 social science journals, based on data from the *Journal Citation Reports* from the Social Science Citation Index). Leydesdorff instead developed a procedure whereby one can choose any particular journal of interest; the program computes the distribution of citations to, and the distribution of citations from, that journal, and selects only those cited and citing journals that involve at least 1% of the total citations (from or to). Generally, 10–20 or so journals represent nearly all of the citations, so all remaining journals are ignored. The “cited” value represents the local impact in terms of citation volume, while the “citing” value represents “how the relevant journal environment is perceived by the collective authors of a given

Table 4 ICA journal citation impact ratings.

ICA journals	2011 impact factor	2013 impact factor	2013 5-year impact factor
<i>Communication Theory</i>	1.20	1.05	1.99
<i>Human Communication Research</i>	2.08	1.89	2.69
<i>Journal of Communication</i>	2.01	2.08	3.2
<i>Journal of Computer-Mediated Communication</i>	1.78	2.02	4.35

Source: 2013 Social Science Journal Citation Reports.

journal” (p. 25) (see www.leydesdorff.net). There are more detailed citation analyses of communication journals^[6–12]

Based on 2004 data, *Communication Theory* is cited primarily by *Communication Research*, *Journal of Communication*, *Human Communication Research*, and *Communication Monographs*. It also has small (but greater than 1%) citations from *Health Communication*, *Media Psychology*, and *Journal of Health Communication*. However, nearly all of its citations go to *Communication Monographs*, with just a few in its local citation environment to *Journal of Personality and Social Psychology*. As *Communication Theory* was new at the time of the 2004 data collection, this network certainly has expanded since then.

Human Communication Research is embedded in a dense and diverse network of citing journals, including *Journal of Communication*, *Human Communication Research*, *Journal of Broadcasting and Electronic Media*, *Journalism and Mass Communication*, *Political Communication*, and, less frequently, *Critical Studies in Mediated Communication*, *International Journal of Public Opinion Research*, *European Journal of Communication*, *Media/Culture/Society*, *New Media & Society*, and *Harvard International Journal of Press and Politics*. Its citing environment (at least 1%) is far less dense, involving *Communication Research*, *Communication Monographs*, *Journal of Communication*, *Journal of Social & Personal Relations*, *European Journal of Social Psychology*, *Journal of Personality and Social Psychology*, *Psychology Bulletin*, and *Personality and Social Psychology Bulletin*.

The *Journal of Communication* is similar to *Human Communication Research* in being embedded in a dense and diverse journal citation environment. Most frequent citers of *Journal of Communication* articles include *Communication Research*, *Human Communication Research*, *Common Monographs*, *Journalism and Mass Communication*, *Journal of Broadcasting and Electronic Media*, *Critical Studies in Media Communication*, and *Political Communication*. Other direct but less frequent citers in the environment include *Journal of Public Opinion Research*, *Media Psychology*, *Harvard Journal of Press and Politics*, *New Media & Society*, *Media/Culture/Society*, and *European Journal of Communication*. Also like *HCR*, *JOC* cites a few primary journals, including *Communication Research*, *Communication Monographs*, *Political Communication*, *Journal of Broadcasting and Electronic Media*, *Journalism and Mass Communication*, *Human Communication Research*, and *Public Opinion Quarterly*.

CONCLUSION

The International Communication Association is a continually growing organization, in terms of research topics

represented by divisions and interest groups, publications, size and internationality of its members, and relationships with other communication associations around the world. It provides the main academic association for primarily social-scientific approaches to the study, teaching, and application of communication research.

ACKNOWLEDGMENTS

I thank Michael Haley and Sam Luna of the International Communication Association for their support and provision of some information for this entry.

International Council of Museums (ICOM)

Patrick J. Boylan

Department of Cultural Policy and Management, City University, London, U.K.

Abstract

The International Council of Museums (ICOM) is the global nongovernmental organization (NGO) representing the interests of museums, galleries, and related heritage institutions and services and their staff. Legally constituted in Paris as an *Association* in November 1946, ICOM is an independent NGO that represents both museum professionals and museums and related institutions and services, with a total of over 27,000 institutional and personal members in 151 countries. The ICOM's working languages are French, English, and Spanish, though national committees or individuals may use other languages in official meetings provided they arrange or pay for the necessary additional translation services.

ORIGIN AND DEVELOPMENT

The ICOM's history can be traced back to the International Museums Office established by the League of Nations, in Paris in 1927 under the League's International Institute of Intellectual Cooperation. Though legally constituted as an intergovernmental body of delegates appointed by Member States of the League, throughout its existence the International Museums Office operated with considerable freedom, acting very much as though it was a nongovernmental body. In particular, it drew on a very wide range of museum professionals and expertise in carrying out many cooperative studies of best practice and museum promotion and advisory programs, covering different museum and gallery activities, as well as work in other heritage areas, such as natural and historic monuments, sites and their conservation.

For example, its Athens Conference of 1931 examined the restoration of historic buildings, while between 1933 and 1939 the Office undertook a major international study of best modern practice relating to the conservation of paintings. Seven decades later these two are seen to have laid the foundations of modern approaches to conservation and restoration in the respective areas. In the case of the paintings study, the findings and recommendations, published in French and English editions in 1939 and 1940,^[1,2] are still regarded as the foundation of scientific conservation and restoration of paintings, in contrast with the "cleaning" (often accompanied by heavy over-painting) of earlier times. Then, as war clouds gathered, and the devastating effect of the latest advances in warfare became clear from the Spanish Civil War, the Office carried out an urgent study of the protection of monuments and works of art in wartime, preparing a substantial practical manual of guidance,^[3] which also included a proposed draft international treaty on cultural protection (much of which was finally to be adopted after World

War II in the 1954 *Hague Convention on the Protection of Cultural Property in the Event of Armed Conflict*.)

The Office also published an international journal, *Museion*, which soon became a most important channel for international communication about museum developments and emerging practice. In addition, the Office launched a multivolume *Traité de Muséographie* covering best practice on all aspects of museum techniques, including the care and maintenance of collections, and many aspects of display and exhibition work. This series remained incomplete due to the outbreak of World War II. Although International Museums Office was in effect closed down in 1940 with the occupation of Paris, it was not formally abolished until after the war.

In October 1946, the new United Nations Educational, Scientific and Cultural Organization (UNESCO) was formally inaugurated in Paris, and started taking over relevant remaining functions and property of the League of Nations, including the library and other property of the International Museums Office. At the same time there were international consultations about establishing a world coordinating body for museums and museum organizations, and in November 1946 representatives of 14 countries met in the Musée du Louvre, Paris, supported by written representations from a further 13 countries, and resolved to create the International Council of Museums (ICOM) as a nongovernmental international *Association*.^[4]

UNESCO, which had already welcomed the proposal, moved immediately to establish formal relations with the new nongovernmental organization (NGO), and in January 1947 the first contract between UNESCO and ICOM was agreed, providing for ICOM to take over responsibility for the museological library of the former International Museums Office as the UNESCO-ICOM Museum Documentation Centre, as well as much of the advisory and coordination role of the former body.

ICOM quickly structured itself on the basis of the familiar NGO pattern. The membership was made up of small national committees of delegates appointed by the countries represented, typically by the national museums, national associations, or other national bodies (including national governments and ministries in the case of less democratic states). In addition to the officers and governing Council, who were elected from the membership, ICOM established international committees of appointed or invited experts (not necessarily members of ICOM itself). Soon these “museum subject” international committees that dealt with particular subjects, (typically different types of museums or collections) were joined by a growing number of interdisciplinary international committees, established to explore and develop best practice in subjects such as museum administration and training, educational services in museums, or the scientific conservation and restoration of collections and works of art.

When first created ICOM continued to cover the whole range of subjects and institutions for which the International Museums Office had been responsible, but over the next two decades or so areas of activity such as national parks, nature reserves, botanic and zoological gardens, and archaeological and historic monuments and sites came more and more within the scope of other international NGOs—particularly, the International Union for the Conservation of Nature (IUCN) in the case of the natural heritage, and the International Council on Monuments and Sites (ICOMOS) in the case of cultural heritage sites and monuments, a trend that was greatly reinforced when the IUCN and ICOMOS were given a special status in relation to these fields by the 1972 World Heritage Convention.

A much more far-reaching change of ICOM’s structure began in the early 1970s. Though the official membership was restricted to those nominated at the national level (and with a maximum of 15 members in each national committee), ICOM’s triennial General Conferences were open to, and increasingly popular with, the world’s museum professionals generally on the payment of the appropriate “Associate” fee. By the time of the 1971 General Conference in Paris and Grenoble the official ICOM members present and entitled to vote were outnumbered several times over by nonvoting Conference participants, who were vocal in their protests about the membership structure. A joint review of the situation was carried out with the participation of representatives of the nonmembers, and at the next General Conference, held in Copenhagen in 1974, ICOM voted to turn itself into an international “membership” organization.

Consequently, from 1975 any museum professional in any country was entitled to join ICOM, becoming automatically a full member of the national committee. Similarly, the international committees, previously small bodies of no more than 30 appointed or elected experts, were reconstituted as unrestricted bodies open to all the

members of ICOM, with each ICOM member entitled to register their membership in any international committee of their choice. Since this fundamental change in the democratic character of its membership, ICOM has grown very rapidly, from less than 1000 members in the early 1970s to 27,000 members today. At the same time, the ICOM’s original list of eight international committees of no more than 30 members each has grown to 30 committees, some of which now have over 1000 members. As of 2008, ICOM also had 17 International Affiliated Organizations and 5 Regional Alliances.

MISSION

The ICOM’s governing *Statutes* including the definition of a museum were also considerably updated as part of the 1974 reforms. In contrast with the long-standing narrow focus (on collection, research, and communication in relation to collections, specimens, and works of art), a museum was declared to have an explicitly social and developmental purpose. According to this new definition, <http://icom.museum/definition.htm> a museum is

... a non-profit making, permanent institution in the service of the society and its development, and open to the public, which acquires, conserves, researches, communicates, and exhibits, for purposes of study, education and enjoyment, material evidence of man and his environment.

The current version of the Statutes of ICOM adopted in the 2007 General Conference describes the mission and purpose of ICOM as follows:^[5]

Mission. The ICOM is the international organization of museums and museum professionals, which is committed to the conservation, the continuation, and the communication to society of the world’s natural and cultural heritage, present and future, tangible and intangible.

Purpose. The ICOM establishes professional and ethical standards for museum activities, makes recommendations on such issues, promotes training, advances knowledge, and raises public cultural awareness through global networks and cooperation programmes. <http://icom.museum/mission.html>

CORE VALUES

Following the approval of the new *Statutes* the previous year, in 2008 ICOM has adopted and published a wide-ranging statement of core values and the vision for the future in the trilingual *Our Global Vision*.^[6] Key provisions include:

Vision

For a world where the importance of the natural and cultural heritage is universally valued

Values

The ICOM values human creativity and its contribution to understanding the past, shaping the present, and planning the future.

The ICOM believes heritage has an innate humanistic value.

The ICOM values global dialogue based on intellectual, cultural, and social diversity.

The ICOM values transparent dialogue including the cross-cultural understanding of human rights.

The ICOM recognizes museums' social responsibility to engage with public issues of social change.

Following the very significant constitutional and policy developments of 2007–2008, ICOM is now recasting its central program, priorities, and budget to match the current objectives and the medium-term plan derived from them, and is urging its international and national committees to contribute very actively to the new approaches.

MEMBERSHIP

ICOM membership is open to all institutions and individuals approved by the appropriate National Committee as complying with the ICOM definitions of a museum or museum professional respectively in the ICOM *Statutes*, on payment of the appropriate annual subscription. (In countries without a National Committee, membership is regulated and managed by the ICOM Secretariat in Paris.)

In July 2008, ICOM had over 27,000 members, including over 1000 institutional members, organized through 118 National Committees, for which a minimum of five paid-up members are required. In addition, there were 100 members in 33 countries and territories that do not have a national committee, so in total ICOM has members in 151 countries. In order to encourage and assist membership development in less developed countries as indicated by appropriate UN and World Bank indexes, there is a 50% reduction in both institutional and individual subscriptions for such countries.

Although 65 of the 118 National Committees currently benefit from this membership subsidy, the percentage of members assisted in this way remains very low, because in most of these countries the ICOM committees are very small due to the limited number of museum professionals and due to the small number and size of museums. As for the Member States of UNESCO that do not currently have an ICOM National Committee, ICOM seeks to ensure that there is an official national correspondent, usually the national museum, the culture ministry or the UNESCO national commission, which receives regular information and publications from ICOM.

Each ICOM member in good standing is entitled to take a full part in the work of both their own national committee as well as one international committee of their choosing, and they can seek and hold office in either or both. Each is also eligible to be nominated by their national or international committee for the triennial election to serve as President of ICOM or one of the officers of ICOM, or as a member of its governing Executive Council. However, with great variations in the number of members in each country and region, ICOM uses an indirect franchise in order to try to achieve a much more balanced geographical representation at its governance level than would be possible with a one member—one vote system (under which Europe might well take most of the elected positions at each triennial election). Therefore, regardless of their size in terms of membership, in all elections each national and international committee exercises five votes, as determined by the committee's members in advance of the vote. (International Affiliated Organizations have three votes each.) In addition, the chairpersons of each national and international committee and international affiliated organization serve *ex officio* as members of ICOM's Advisory Committee.

National committees elect their own national officers and decide their own program of activities. In some countries, the ICOM National Committee serves as a national museums association, undertaking a wide range of programs, liaison with government on, for example, museum and heritage policy and financing, and activities such as meetings, conferences, and publishing. However, where there is a large, long-established, and well-developed national association, as in the United States or United Kingdom already undertaking much of this work, the ICOM National Committee will typically have a more limited role—for example, concentrating on international rather than domestic affairs and on membership promotion, recruitment, and management on behalf of ICOM internationally.

COOPERATIVE PARTNERSHIPS

The ICOM's key, and longest-established, partnership is with UNESCO; the first formal agreement between the two being adopted less than 3 months after the two organizations were formally established in the Autumn of 1946. For much of the following six decades, ICOM and its work was subsidized directly by UNESCO, and its Secretariat was housed within UNESCO offices. Over the past two decades or so UNESCO's policy toward its former Category A NGOs has changed, with a reduction and finally a withdrawal of operating subsidies and their replacement by opportunities to undertake contract work for UNESCO. More recently because of UNESCO's own office space problems, the ICOM Secretariat had to move out of the free accommodation in the *Maison de l'UNESCO* into rented accommodation nearby.

Historically, ICOM has undertaken leading roles in the research and editing of UNESCO's cultural heritage publications programs, notably the quarterly journal *Museum* (now *Museum International*), and continues to run the UNESCO-ICOM Museum Information Centre (the successor to Documentation Centre, established in 1947). The ICOM has been a close partner in many UNESCO cultural heritage campaigns and initiatives, particularly museum development assistance and staff training programs in many parts of the world. For example, the world's first *Basic Syllabus for Museum Professional Training* was drawn up by ICOM for UNESCO in 1971, while the two bodies continue to work closely together in the new UNESCO/ICOM Museum Training Programme begun in 2004, initially as a part of the UN's proposed Iraq Reconstruction Programme, but later made available more generally with both printed and online resources centered around *Running a Museum: A Practical Handbook* (original editions in English, Arabic, and French, 2005), and a program of UNESCO training workshops run with ICOM participation. For details of the UNESCO/ICOM Museum Training Programme and links to its publications, etc., see UNESCO's Web site.^[7]

ICOM has also been, and remains today, closely involved with a number of UNESCO's most important cultural heritage protection and promotion programs and international conventions, notably

- The 1954 *Convention on the Protection of Cultural Property in the Event of Armed Conflict* ("Hague Convention") of 1954 and its 1954 and 1999 *Protocols*.
- The UNESCO Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property, 1970.
- The UNESCO Convention for the Safeguarding of the Intangible Cultural Heritage, 2003.

In each case, ICOM is accredited to an advisory body attending their related Intergovernmental Committees.

Other important links with international intergovernmental organizations include a long-standing partnership with the Rome-based International Centre for the Study of the Preservation and Restoration of Cultural Property (ICCROM) ever since its establishment in 1959, and ICOM's status as an NGO accredited to the Economic and Social Council of the United Nations (ECOSOC). Most recently, after several years of informal links and communications, in 2007 ICOM established a formal partnership with the World Intellectual Property Organization (WIPO), and is currently working closely with WIPO's Traditional Knowledge, Genetic Resources, and Traditional Cultural Expressions/Folklore studies in particular.

The ICOM also has close relations with many NGOs. At the national level, there are almost always close links and cooperation with any national museum associations and similar bodies, while a number of the International

Committees similarly have links with other international academic and professional bodies in their various fields of interest.

At the international level, ICOM has always had close relations with the International Council on Monuments and Sites (ICOMOS) since its formation in 1965; the two organizations have mutual observer status representation at each other's conferences and executive councils. There have also been links for some years between some equivalent international committees of the two bodies. In June 2008, it was agreed that this kind of twinning cooperation should be established between all relevant ICOM and ICOMOS international committees.

From 1967 onward, ICOM welcomed and actively supported various initiatives toward international cooperation between the growing number of national federations of Friends of Museums organizations. Since the formalizing of this with the establishment of the World Federation of Friends of Museums (WFFM) as a new international NGO in 1975, ICOM has always been an active partner and enthusiastic supporter of the organization's work and its triennial Congresses. Today the WFFM brings together almost 50 national Friends organizations, and represents an estimated two million individual members of Friends organizations around the world.

In 1995, ICOM and ICOMOS entered into a formal cooperation agreement with two other UNESCO-linked NGOs: the International Federation of Library Associations and Institutions (IFLA) and the International Council on Archives through the establishment of the International Committee of the Blue Shield (ICBS) as a standing joint committee to facilitate professional and technical cooperation and coordination in relation to all kinds of emergencies affecting, or threatening, any kind of cultural property, whether building or site, library, archive, or a museum or art collection. More recently, the four ICBS organizations have been joined by a fifth: the Coordinating Council of Audiovisual Archives Associations (CCAAA).

GOVERNANCE

ICOM follows the fairly standard structure of an Association under the French *Loi des Associations de 1 juillet de 1901*. The ultimate authority is the annual General Assembly, which consists of all individual, student, supporting, and honorary members and the designated representatives of institutional members. However, only those individual members and representatives of institutional members who have been designated as voting delegates by National Committees, International Committee, and Affiliated Organization have the right to vote. The General Assembly adopts and amends the *Statutes*, its own Rules of Procedure, determines the overall policy and program of the organization and the location and themes of the Triennial General Conferences, and approves the budget, rates

of subscription and the audited accounts. Once every three years, the General Assembly also elects the President, other Officers, and the Executive Council.

The President is elected for a 3-year term of office and can be reelected for a second term of the same duration. The President sets the strategic orientations for the activities of ICOM in its capacity as an international organization representing museums and museum professionals. The President represents ICOM in all civil acts and the signature of the President binds ICOM in contracts and agreements with third parties. The President convenes and chairs the meetings of the General Assembly and the Executive Council, and after consultation with the Executive Council as appropriate, also makes appointments to Standing Committees and representatives of ICOM to other bodies, conferences, meetings, etc.

The Executive Council is the decision-making body of ICOM, and consists of a total of 15 elected members: the President, 2 Vice-Presidents, Treasurer, and 11 other members, all elected once every 3 years in the General Assembly, together with the Chairperson of the Advisory Committee as an *ex officio* member.

The Council meets in ordinary session at least twice a year, one of these meetings being held in association with the annual Ordinary General Assembly, at the same time and place. The Executive Council ensures the good management of ICOM, overseeing the various resources of ICOM (financial, human, intellectual, and technical) and their development, safeguarding ICOM's reputation, international esteem, and public regard. The President, Vice-Presidents, and the Treasurer form the Bureau of the Executive Council, which has the power to resolve urgent issues, reporting on any action taken to the full Executive Council as soon as possible.

The Advisory Committee consists of the Chairpersons (or their appointed representatives) of every National and International Committee, Regional Alliance, and Affiliated Organization, and meets at least once a year in ordinary session, around the same date and at the same location as one of the Executive Council meetings. The Advisory Committee advises the Executive Council and the General Assembly on matters concerning the policies, programs, procedures, and finances of ICOM, and may propose amendments to the *Statutes*. It also advises on matters and activities in the general interest of ICOM referred to it by the Executive Council or the General Assembly.

The Chairperson and two Vice-Chairpersons of the Advisory Committee are elected by the membership of the Committee for a 3-year term of office, and may serve two consecutive terms. The Chairperson of the Advisory Committee convenes and chairs the meetings of the Committee, serves as an *ex officio* member of the Executive Council and as the Elections Officer of ICOM and finally, as an *ex officio* member of the Board of all Regional Alliances.

In addition to the Advisory Committee and the National and International Committees, ICOM has a small number of specialist Standing Committees, appointed for 3 year terms by the President after consultation with the Advisory Committee and Executive Council. Each has a specific remit and a membership of around 10 appointed members, with the President and Director General as *ex officio* members in addition.

The Chairperson and members of the Ethics Committee, first established in 1986, are eminent senior members of ICOM. The Committee's mission is to monitor the provisions and application of the ICOM Code of Ethics for Museums (first adopted in 1986 as the ICOM Code of Professional Ethics, and last revised by on the recommendation of the Committee in 2006)^[8] and to advise the Executive Council in relation to the apparent or alleged serious violations of the Code. It also reviews other Codes of Ethics that may be developed by the International Committees concerning their special fields of interest and/or expertise, and reports to the Executive Council and General Assembly on any matters relating to the Code of Ethics or its application that the Committee thinks appropriate.

The Legal Affairs Committee was established in 2002 in the light of the increasingly complex legal and intellectual property matters that are seen to be affecting museums and the work of museum professional. In addition to ICOM members, the Committee is fortunate to have on it a number of distinguished specialist lawyers who volunteer their services to ICOM through the Committee. In addition to acting as an internal advisory body to ICOM, and in particular to the President, Director General, Executive Council, Advisory Committee and International Committees and its component bodies on legal questions relating to their governance and administration, the Committee is mandated to examine on its own initiative the broader environment of evolving legal issues affecting museums, museum professionals, and the wider cultural heritage sector today.

Two of the major issues currently being worked on by the Committee are a review of current trends in intellectual property law and its application so far as these relate to museums and related bodies, and the launching of a system of dispute resolution through mediation rather than court actions over disputes concerning museums, for example, over the ownership or the claim for a return of cultural objects in museum collections. The four Standing Committees each meet once or twice a year in plenary session, but nowadays carry out much of their business throughout the year by electronic communication.

Two other Standing Committees are particularly concerned with ICOM's internal affairs. The Finance and Resources Committee, established in 2002, reviews and advises on longer-term financial and investment policy and practice, while the Standing Committee on International Committees assists the Advisory Committee and

Executive Council in reviewing policy and practice in relation to the establishment and operation of ICOM's International Committees.

The work of ICOM generally, and in particular that of the General Assembly, Executive Council, Bureau and Advisory Committee, is supported by a small Paris-based Operational Secretariat, consisting of the Director General and other staff members of ICOM, and which is the operational centre of ICOM. The Secretariat evaluates, initiates, and manages operational programs and contracts, manages membership, finances, the UNESCO-ICOM Information Centre and ICOM's publications, and promotes the identity of the Organization.

The Director General is the Chief Executive Officer, appointed by the Executive Council, is responsible to the Council for the efficient and effective management of ICOM, for the resources required for the functioning of ICOM and the daily operations of the Secretariat. The Director General also has important responsibilities for promoting the interests of ICOM and communication both externally, to partner organizations, other bodies and the media, and internally, to ICOM's members and committees. On a day-to-day basis, the Director General reports directly to the President of ICOM.

INTERNATIONAL COMMITTEES AND AFFILIATED ORGANIZATIONS

It is through its International Committees that ICOM achieves its major objectives and programs: the exchange of scientific information at an international level, the development of professional standards, and the adoption of rules and recommendations on best practice relating to their areas of specialization and expertise.

All individual members of ICOM (and representatives of institutional members) are entitled to register as full ("voting") members in any one International Committee of their choice, and to seek and hold office in their chosen Committee. In addition, a member may attend meetings of any other Committee (on payment of the required conference fee if applicable). Subject to the *Statutes of ICOM* and the *Model Rules for International Committees*, each is free to organize and run itself as its voting members decide in terms of meetings, research and other programs, committee publications, etc. However, each Committee is expected to hold a professional meeting at least once a year, and in the year of the Triennial General Conference of ICOM that meeting should be held within the overall program of the General Conference.

The 30 International Committees vary greatly in size. Some are small specialist groups with less than a 100 members focusing on a very specific area of museum collections or practices, while other are many times larger. The Conservation Committee (ICOMCC) is so big (with over a thousand members) and so wide in its scope, that in

addition to its participation in the triennial General Conference it organizes a major international scientific conference of its own every 3 years (normally in the year following the ICOM Triennial Conference). Though there is no formal distinction between them, in practice the International Committees can be divided into two categories: those that focus on a specific type of museum or museum collection, and what may be termed as interdisciplinary committees that deal with a specific museum-related discipline relevant to most or all kinds of museum or similar institution.

The following are the 19 types of museum- or collection-based International Committees: CAMOC—Collections and Activities of Museums of Cities, CIMAM—Museums and Collections of Modern Art, CIMCIM—Museums and Collections of Musical Instruments, CIPEG—Egyptology, CIMUSET—Museums and Collections of Science and Technology, COSTUME—Museums and Collections of Costume, DEMHIST—Historic House Museums, GLASS—Museums and Collections of Glass, ICDAD—Museums and Collections of Decorative Arts and Design, ICFA—Museums and Collections of Fine Arts, ICLM—Literary Museums, ICME—Museums and Collections of Ethnography, ICOMAM—Museums of Arms and Military History, ICMEMO—Memorial Museums in Remembrance of the Victims of Public Crimes, ICOMON—Money and Banking Museums, ICMAH—Museums and Collections of Archaeology and History, ICR—Regional Museums, NATHIST—Museums and Collections of Natural History, and UMAC—University Museums and Collections.

The following are the 11 interdisciplinary subject International Committees: AVICOM—Audiovisual, Image and Sound Technologies, CECA—Education and Cultural Action, CIDOC—Documentation, ICAMT—Architecture and Museum Techniques, ICEE—Exhibition Exchange, ICOFOM—Museology, ICOM-CC—Conservation, ICMS—Security, ICTOP—Training of Personnel, INTERCOM—Management, and MPR—Marketing and Public Relations.

National Committees and their members in certain regions of the world are also grouped into a number of ICOM Regional Alliances as follows: ASPAC—Asia and Pacific, ICOM-ARAB (Middle East and North Africa), ICOM-EUROPE, ICOM-SEE (South-East Europe), and LAC—Latin America and Caribbean.

ICOM also has 17 International Affiliated Organizations: AEOM—Association of European Open-Air Museums, AFRICOM—International Council of African Museums, AIMA—International Association of Agricultural Museums, AMOI—Association of Museums of the Indian Ocean, CAM—Commonwealth Association of Museums, HO!E—Hands On! Europe Association of Children's Museums, IACM—International Association of Custom Museums, IAMFA—International Association of Museum Facility Administrators, IAMH—International

Association of Museums of History, IATM—International Association of Transport and Communication Museums, ICAM—International Confederation of Architectural Museums, ICMM—International Congress of Maritime Museums, MAC—Museums Association of Caribbean, MINOM—International Movement for a New Museology, PIMA—Pacific Islands Museums Association, SADCAMM—Southern Africa Development Community Association of Museums and Monuments, SIBMAS—International Association of Libraries and Museums of the Performing Arts.

In recent years, there has been a growing, and welcome, trend for two or more international committees to meet together to consider matters of mutual interest, and also to include other relevant organizations in their annual meetings. With the recent agreement to promote closer cooperation between the International Committees of ICOM and the International Scientific Committees of ICOMOS more joint meetings are anticipated.

ACTIVITIES

The highlight of ICOM's program is the General Conference, held once every 3 years in different parts of the world (most recently Melbourne 1998, Barcelona 2001, Seoul 2004, and Vienna 2007, with the next in Shanghai in 2010), and which typically attracts well over 2000 members.

Though the conference as such lasts 6 days, it is usually preceded the previous week by preparatory meetings of the Executive Council and Advisory Committee as well as meetings of the four Standing Committees, of any *ad hoc* working or project groups, and often of the Boards of the International Committees and Regional Alliances. The Conference begins with an opening ceremony involving the representatives of the host country and the leading partner organizations, including the Director-General of UNESCO or his personal representative. The rest of the opening day is devoted to plenary sessions and discussions on the chosen General Conference theme, led by invited distinguished keynote speakers and expert panels.

Days 2–4 are primarily devoted to sessions of the 30 International Committees, which are open to all registered Conference participants, and it is expected that at least some of these sessions will address the General Conference theme from the perspective of each Committee's specialization and field of expertise. Most Committees also arrange visits to museums or other institutions of particular interest to the Committee's specialist members. During the 3 days, the International Committees also set aside up to half a day for their triennial business meeting. At this all voting members of the Committee (including absent members represented by proxy) consider the administrative and financial reports of its Chairperson, Treasurer, and Board, adopt the forward program of

meetings and activities, elect Officers and Board for the following 3 years, and agree to the preparations for the ICOM General Assembly, including mandating the Committee's voting members on matters to be decided at the forthcoming ICOM General Assembly. In parallel with the 3 days of meetings of the International Committees there is always a large Trade Fair presenting museum and related supplies and services.

Day 5 of the Triennial General Conference is traditionally set aside for whole day study visits, while the final day is the meeting of the General Assembly of ICOM as a whole at which both reports on the past triennial period and proposals for the future policies, programs, and priorities are considered and adopted. Voting for the election of the President, Vice-Presidents, Treasurer, and Executive Council members for the following 3 years takes place throughout the week, and the results of the elections are announced in the General Assembly. Finally, but by no means least, the General Assembly debates, and if it thinks fit, adopts Resolutions setting out ICOM's policies and objectives, or responding to matters of concern. The full texts of the almost 400 General Assembly Resolutions from the founding meeting of 1946 to the most recent (Vienna 2007), available on line,^[9] provide a comprehensive overview of the development of ICOM's policies and objectives, and indeed the changing focus of the principal concerns and priorities of ICOM over more than six decades.

ICOM also organizes important thematic conferences and seminars from time to time, most of which have played a significant role in developing policy and providing advice on professional practice over many areas through the production of conference or seminar publications. Examples have included the review of museum needs in Africa (in Benin, Ghana, and Togo), in Arab countries (in Amman, Jordan), on heritage protection and the struggle against illicit trafficking in cultural property (Tunis), on museums, heritage and tourism (in La Paz, Bolivia), and museum emergency planning and response (Hyderabad, India).

However, while the General Conference is very important, in terms of the total professional impact it is probably fair to say that the annual meetings of the 30 International Committees amount to ICOM's greatest impact on museums and the professional overall. The Committees aim to meet in all parts of the world, usually for a full week or more, with a program including lectures, discussions, and study visits to local museum of special interest. Many of these meetings have developed and promoted important advances in policy and practice.

ICOM has also undertaken many significant campaigns, most notably in relation to the protection of cultural property and the struggle against illicit trafficking in stolen, looted, or otherwise illegally transferred antiquities, works of art, and other cultural property. Recognizing that museums have often been the final destination of such material either directly through dealers or indirectly through

collectors who eventually donate their collections to museums, as long ago as 1970 ICOM adopted a policy statement on the Ethics of Acquisition, and this was further developed in the 1986 ICOM Code of Professional Ethics. The ICOM also works closely with other international bodies, notably UNESCO, but also INTERPOL and the International Customs Union, in this work, and has published a number of *One Hundred Missing Objects* . . . books describing and illustrating typical missing items from particular countries or regions: so far these cover Angkor (Cambodia), Africa, Latin America, and South-East Europe, while “Red Lists” have been published for Afghanistan and Iraq.

PUBLICATIONS AND MEDIA

Since its establishment, ICOM has produced a regular newsletter for members and interested persons: *Nouvelles de l'ICOM/ICOM News* (with a Spanish edition as well since 1999). During its six decades of existence, ICOM has also published a very large number of books and reports, some produced centrally, but the majority have been published by the International and National Committees, most of which have also produced journals or newsletters. A complete catalog of ICOM publications from 1947 to date is available online on the ICOM Web site. For details of the online catalog of ICOM publications, see ICOM's Web site.^[10]

ICOM also moved into new media at a relatively early date, with the launch of both its overall Internet policy and first Web site at the Stavanger General Conference in 1995. Most International Committees and many National Committees have since become very active in this field with their own Web sites (linked to the central ICOM Web site) and electronic publications. One of the long-term aims of the 1995 policy was to seek to establish “dot museum” as a top-level Internet domain controlled by the profession to ensure that only organizations deserving the title should be able to use the domain, and in 2000 Internet

Corporation for Assigned Names and Numbers (ICANN), the controlling body for the Internet, approved the establishment of the new domain.

International Council on Archives (ICA)

Perrine Canavaggio

International Council on Archives, Paris, France

Marcel Caya

Department of History, University of Quebec at Montreal (UQAM), Montreal, Quebec, Canada

Abstract

Founded in 1948, the International Council on Archives (ICA) is an international body representing the world community of records and archives managers. Its membership includes national archives administrations, professional associations, archival institutions of regional and local authorities, and private organizations, as well as individual archivists. An independent, nongovernmental, not-for-profit organization, the ICA is headquartered in Paris, France. As the leading international nongovernmental organization (NGO) for archives and archivists, ICA continues to work in cooperation with UNESCO and NGOs in related areas to realize shared objectives.

THE INTERNATIONAL COUNCIL ON ARCHIVES

The International Council on Archives (ICA) is a nongovernmental organization (NGO) bringing together national archive administrations, professional associations of archivists, regional and local archives, and archives of other organizations as well as individual archivists. As the professional organization for the world archival community, ICA has a global network of around 1500 institutional members in 195 countries and territories, and over 270 archivists and records managers as individual members. ICA has its registered office in Paris, France; it is a nonprofit organization set up under French law.

THE BEGINNINGS

The idea for an ICA had long been around. The Institute for Intellectual Cooperation, acting under the aegis of the League of Nations, made the first attempt after World War I by creating a Permanent Consultative Committee on archives in 1931. This committee published the first *International Guide on Archives* in 1934. Several factors contributed to the creation of the ICA in 1948. The first was the choice of Paris as the site of the headquarters of the United Nations Educational, Scientific, and Cultural Organization (UNESCO), which in the immediate post-war years was concerned with promoting NGOs in its field. In 1946, under the influence of an American conservator Chauncey J. Hamlin, an international council for museums (ICOM) had been set up. On a similar model, following the distribution of proposals at the international level in the autumn of 1947, and under the influence and tenacity of Dr. Solon J. Buck, then Archivist of the United

States, a small group of experts met in Paris and agreed on June 9, 1948, to establish an “International Council on Archives,” with the then Director-General of the Archives de France, Charles Samaran, as chairman. Charles Braibant succeeded him in 1950. The first assembly of the Council was held following a meeting of the group of experts in Paris, on August 21 and 22, 1950, at the UNESCO headquarters.

During its first 50 years, ICA functioned more or less as a centralized international organization, thanks to the support of UNESCO with leadership provided by the Paris Secretariat and the national archivists of member countries. (Thanks to the hospitality of the Archives de France, the Paris Secretariat has been housed since 1960 at the Archives nationales, 60 rue des Francs-Bourgeois in Paris.) Its various committees brought together experts in many fields to undertake study and research, prepare, and publish reports on various archival functions and issues as well as provide contents for various meetings including the quadrennial Congress and the International Conference of the Round Table on Archives (CITRA).

The first International Congress on Archives was held in Paris, from August 23 to 26, 1950; it brought together 360 archivists from 35 countries. The first Round Table on Archives was held in Paris in 1954 and, since then, meets every year except on the year a Congress is held.

Archivum, the first official journal of ICA, was created with the publication of the proceedings of the first Congress in 1950. It soon extended its contents to cover, in addition to the proceedings of congresses, the International Archival Bibliography, the International Directory of Archives, archival legislation around the world, and special issues on specific theme, such as notarial archives, municipal archives, etc.

Regional branches and sections were eventually created to allow the active participation of more countries sharing similar conditions: from 1968 to 1982, eight regional branches were created. With the creation in 1976 of the Section of Professional Archivists Associations (SPA) and the Section of International Organizations (SIO), sections brought together professionals sharing similar problems; the creation of the Section of Municipal Archives (SMA) inaugurated a trend away from central government archives which led to the creation of several other sections based on types of archives.

Since its creation, ICA has cooperated regularly with its sister organizations, particularly IFLA, ICOM, and ICOMOS. In this context, it has actively participated in the activities of the International Committee of the Blue Shield of which it is a founding member.

Created in 1996, the International Committee of the Blue Shield (ICBS) is formed by five NGOs: ICA, the Coordinating Council of Audiovisual Archives Associations (CCAAA), the International Council of Museums (ICOM), the International Council on Monuments and Sites (ICOMOS), and the International Federation of Library Associations and Institutions (IFLA) share the mission to work for the protection of the world's cultural heritage by coordinating preparations to meet and respond to emergency situations. Its main objectives are to facilitate international responses to threats or emergencies threatening cultural property and to encourage safeguarding and respect for cultural property especially by promoting risk preparedness. The Blue Shield is the symbol equivalent of the Red Cross used for marking cultural sites to be protected from attack in the event of armed conflict.

1948–1989 THE COLD WAR

Thanks to the ICA, the cold war did not prevail in the archives field. The Council played the unique role of establishing a forum for professional meeting and exchange between archivists from East and West as well as promoting discussion and cooperation beyond political divisions. These exchanges focused on issues of common interest, particularly in three technical areas dealing with microfilm, restoration of documents, and buildings. The ICA developed those exchanges largely with the intellectual and financial help of UNESCO during that period.

The main objective then was to open access to archives to allow historians to compare sources from diverse provenances; the archives of countries and institutions often convey significance beyond their own frontiers and activities; it is notably the case with diplomatic, military, university, and bank archives as much as it is the case with the records of international organizations which can inform on partners and users. In order to improve access, ICA has always promoted cooperation through two different while complementary means:

- *Microfilm reprography* (security, acquisition, and replacement) to complement existing archival holdings, reconstitute incomplete ones, settle or lessen legal dispute; the ICA has thus promoted bilateral agreements to microfilm in order to remedy the absence or the lack of complete textual resources.
- Publication of the *Guides to the Sources of the History of Nations* in three series from 1960 to 1970 to enable researchers to know the sources preserved outside their region by other countries, to identify them, and to promote their processing. Sixty volumes were thus published between 1958 and 1984; they provide an inventory of sources concerning Latin America, Africa, and Asia.

From 1960, during a period when many countries gained their independence and others put an end to their colonial power, priority was given to the development of archives in the new countries with a number of programs created for developing countries and the creation of regional branches to bring them together. A Committee on Archival Development (ICA/CAD) was formed in 1970. It operated the International Archival Development Fund (FIDA), which received major donations for some developing countries (Algeria, Iran, Nigeria, and Yugoslavia). While it enabled seminars and study missions to be held, it was not given the continuous support it needed. Since the beginning of the 1970s, almost all the developing countries have established archival services.

Thanks to its close cooperation with ICA, UNESCO has published a series of archival studies known as the Records and Archives Management Program (RAMP). More than 100 studies dealt with basic professional issues covering records and archives management in areas such as preservation, legislation, archival theory, and practices. They were authored by international experts and published in English, French, and Spanish. They have been valued a great deal, notably by professionals in developing countries. Many of these studies have been reissued on CD by UNESCO in 2008. Although some studies are now dated as a result of technological advances, others remain highly topical. The CD is intended as a working guide of selected RAMP studies and, as such, contains only a limited number of titles. The complete series can be accessed from UNESCO's Web site at: http://unesdoc.unesco.org/ulis/search_form.html.

At the same time, a long-term legal discussion was maintained within ICA to respond to the major and recurrent issue of the unresolved archival legal disputes, inherited from the past. While traditionally, articles dealing with archives were included in treaties during the seventeenth to the nineteenth centuries, no peace treaty was signed in 1945 with the defeated countries; therefore, many issues have never been settled and no systematic effort was made to return archival holdings seized during the hostilities. The archival question was not included in

the independence agreements with the new countries; new States found themselves without documentation for their historic rights.

The building and reconstitution of the archival heritage of those countries whose archives, in great part, are held in repositories of developed countries has been debated many times during meetings of the CITRA. The Declaration of the Executive Board at Guanzhou in 1995 on the settlement of archival claims has recommended to take a pragmatic approach; in cooperation with UNESCO, the ICA has provided a set of legal concepts and principles such as the inalienability and imprescriptibility of public records, provenance, and respect for the integrity of archival fonds, the right of access, and the right of reproduction. In order to make these rights effective and prevent the splitting of archival fonds, UNESCO has recommended the introduction of the concept of shared heritage since 1979.

The Council of Europe has published in 1997 a reference document prepared by the ICA Committee on Archival Legal Matters to facilitate the settlement of archival claims arising from war, military occupancy, and States succession.

With the end of the USSR and of several totalitarian (or repressive) regimes in the world, great masses of archives from police and security units of those regimes appeared and new legal problems emerged, particularly their access; it was urgent to help archivists work in a democratic environment and to reinforce the role and position of the National Archives. It is in that context that the issue of professional ethics was launched in 1992 within the Section of Professional Associations (SPA) generating the ICA Code of Ethics adopted in 1996. At the present time SPA is considering a revision to this Code in the light of a member survey.

The Council of Europe has helped ICA a great deal since 1993 to promote the modernization of archives in Europe through East–West seminars and financial support for expert missions. ICA has also invested greatly in promoting the accessibility of archives. This effort was reinforced in 2000 by Recommendation no. R 13 of the Council of Europe about a European Policy on access to archives and in 2001 on the teaching of history. The Council of Europe has adopted the first intergovernmental standard on the issue and recognized the right of people to know their history as a cultural human right.

ICA TODAY

From an association of directors of national institutions, the ICA has evolved toward a more complex organization bringing together professional associations and individual archivists interested in researching, developing, and sharing their full range of archival expertise. As a result, the ICA has become the professional organization for the world archival community, dedicated to promoting

the preservation, development, and use of the world's archival heritage.

The activities of the ICA complement those of national associations and institutions and continue to be an exclusive source and channel of professional expertise in those regions where national associations do not yet exist.

As the leading international NGO for archives and archivists, ICA continues to work in cooperation with UNESCO and NGOs in related areas to realize shared objectives.

Mission and Values

ICA's current mission and core values were officially adopted in 2004 and 2008. While it continues to focus on the promotion of archives and the role of archivists in achieving high standards of governance and democracy, it makes room for the inclusion of improved records management as a precondition of the creation of authentic, accurate, and meaningful archives.

As stated in the ICA Constitution, the mission of the International Council on Archives is:

to promote the preservation and use of archives around the world. In pursuing this mission, ICA works for the protection and enhancement of the memory of the world and to improve communication while respecting cultural diversity. (Preamble ICA Constitution)

To promote the preservation and use of archives around the world, ICA aims to support the management and use of current records as well as archives and the preservation of the archival heritage, by sharing experiences, research, and ideas on professional archival and records management matters, and on the management and organization of archival institutions. Its objectives are to:

- Encourage and support the development of archives in all countries, in cooperation with other organizations, including international agencies, governmental, and nongovernmental.
- Promote, organize, and coordinate best practice, the development of standards and other activities in the field of records and archives management.
- Establish, maintain, and strengthen relations between archivists of all countries and between all institutions, professional bodies, and other organizations, public and private, wherever located, which are concerned with the administration or preservation of records and archives, or with the professional training of archivists, especially through the exchange of information.
- Facilitate the interpretation and use of archives by making their content more widely known and by encouraging greater access to them.

Therefore, as expressed in its 2008 Strategic Directions, ICA promotes the central role of record-keeping and

archives in protecting the rights of individuals and states, and in supporting democracy and good governance. It works for the effective management of archives from the moment of their creation, the permanent preservation of archives as the documented memory of nations and societies, and the widest possible public access to that memory. It advocates the importance of archives management to policy-makers.

It sees its role as providing opportunities for professional contact, information exchanges, research, and education, which support records and archives professionals and other partners throughout the world. It also endeavors to take a leading part in developing best practices and standards for the records and archives profession.

Its core values were also revised and stated in the 2008 Strategic Directions document. They are expressed in the following statement: "In fulfilling ICA's mission, we strive to uphold the values of equality, diversity, openness, and mutual respect across national boundaries and cultural traditions. We will be as transparent as possible to our members and provide them with full value in return for their contributions (whether monetary or in kind) to the organization."

Definition of Archives

The current evolution of ICA has followed quite closely the extraordinary developments of the profession in recent years. While the English definition of the word "archives" remains focused on materials of enduring value, most archivists, even in the English-speaking world, are also concerned with the management of current records. At the international level, this widening of the focus has never been a problem since the words "records" and "archives" are often used interchangeably; in French, the word "archives" means both current records and records of enduring value.

The Glossary of the Society of American Archivists defines archives as "Materials created or received by a person, family, or organization, public or private, in the conduct of their affairs and preserved because of the enduring value contained in the information they contain or as evidence of the functions and responsibilities of their creator, especially those materials maintained using the principles of provenance, original order, and collective control; permanent records." Other meanings also provide definitions of archives as organizations, buildings, professional discipline, and collection of papers.

More importantly, the archival community has traditionally been more concerned by the recognition of the special character of records and archives as the "Materials created or received by a person, family, or organization, public or private, in the conduct of their affairs" preserved because of the value (not only enduring) of the information they contain or as evidence of the functions and responsibilities of their creator.

Members

From 17 countries in 1949–1950, the membership had grown to 117 countries in 1984 and to 195 countries and territories in 2008.

ICA now has a global network of around 1500 institutional members and over 250 individual members. Its membership comprises public and private archival institutions, associations, and individual members:

- Central archives directorates or national archival institutions: 236 members.
- National associations of professionals: 81 members.
- International associations: 42 members.
- Institutions concerned with, or interested in, the administration or preservation of records and archives, or with archival training and education: 873 members.
- Individuals working in the field of the administration or preservation of records and archives, or of the archival training and education: 258 individual members.

In order to give its members increased opportunities to be involved in projects, the members of ICA can participate in two types of groupings: the regional branches and the sections.

Regional Branches

Through its 13 branches, ICA provides a basis for exchange and common initiatives at the regional level, more closely aligned to specific needs resulting from particular environments. Members of ICA wishing to further the aims of ICA and to strengthen cooperation within a particular geographical area may group themselves into regional branches. The global network comprises 12 regional branches and one regional network; their creation was developed over a period of almost 40 years.

1968 SARBICA (Southeast Asian Regional Branch).

1969 ESARBICA (Eastern and Southern Africa Regional Branch).

1972 ARBICA (Arab Regional Branch).

1975 CARBICA (Caribbean Regional Branch).

1976 SWARBICA (South and West Asian Regional Branch).

1976 ALA (Association of Latin American Archives).

1977 WARBICA (West African Regional Branch).

1981 PARBICA (Pacific Regional Branch).

1982 CENARBICA (Central African Regional Branch).

1993 EASTICA (East Asian Regional Branch).

2000 EURASICA (Eurasia Regional Branch).

2001 EURBICA (European Regional Branch).

2004 NAANICA (North American Archival Network).

Regional branches have separate leadership and programs. For example, PARBICA has its own Work Plan 2008–2010 which is in line with the ICA Strategic Direction. It is

developing a good governance toolkit project which will be translated and adapted in other languages. EURBICA has three ongoing main projects: EURONOMOS, a database providing the European archival legislation online; a methodology to train the trainers in records management; and a European competency model.

Sections

Institutional or individual members of ICA sharing common professional interests or activities and wishing to further the aims of ICA and to strengthen cooperation within their professional competence may group themselves into sections. ICA members may join more than one section. ICA's sections are established along professional interests; they address other types of concerns and stimulate research and information exchange in more specific areas.

There are presently 11 full-fledged sections; two more are provisional until it is demonstrated that there is sufficient interest to give them a permanent status.

- SAE—Section for Archival Education and Training: 43 members.
- SAN—Section on Notarial Records: 8 members.
- SAR—Section on Architectural Records: 21 members.
- SBL—Section for Business and Labour Archives: 100 members.
- SIO—Section for Archivists of International Organizations: 42 members.
- SKR—Section for Archives of Churches and Religious Denominations: 53 members.
- SMA—Section for Municipal Archives: 152 members.
- SPA—Section of Records Management and Archival Professional Associations: 81 members.
- SPO—Section on Sports Archives: 14 members.
- SPP—Section for Archives of Parliaments and Political Parties: 94 members.
- SUV—Section on University and Research Institution Archives: 161 members.
- SLA—Provisional Section on Literature and Art Archives: 6 members.
- SSG—Provisional Section on Sigillography: 10 members.

Each section elects a bureau and draws up its program of activities in cooperation with the Programme Commission of ICA.

Project Committees and Working Groups

ICA also forms committees and groups at various levels to work on specific projects and activities in support of the objectives defined by its Strategic Direction. Expert committees on various specific archival issues created since 1959 were abolished in 2004. They

were replaced by project working groups or ad hoc committees with short and dedicated mandate under the Programme Commission. Only one committee [Committee on Best Practices and Standards (ICA/CBPS)] is currently active as the professional home for the maintenance and development of standards and best practices and related activity within ICA. Building on its strength in the area of archival description, this Committee is currently expanding its scope to cover more aspects of professional activity.

FIDA: International Archival Development Fund

FIDA was set up in 1975 as a means of attracting funds internationally. However, in recent years, difficult financial conditions have limited what has been raised. On a smaller scale, ICA used its own resources to assist small projects, such as expert missions and regional meetings, where matching funds were available locally. (Since 2000, 5% of the dues of all members are set aside for FIDA.) Thanks to the additional contribution by a number of countries, it is able to support new initiatives, particularly training programs in less-developed countries.

Governance

The highest decision-making body in ICA is the Annual General Meeting which meets once a year during the Congress or the CITRA; it consists of delegates from national institutions and associations. Between Annual General Meetings, the government of ICA is in the hands of the Executive Board, which includes chairs of all regional branches and most sections, thus ensuring broad representation internationally and professionally.

The work of the Executive Board is supported by three commissions:

- The Management Commission brings together the ICA President and Vice-President in addition to the President of a Regional Branch, the Secretary General, and the Deputy Secretary Generals; it is responsible for the preparation of Executive Board meetings and making management decisions between meetings of the Executive Board.
- The Programme Commission consists of the Vice-President Programme, who acts as chair, and of members appointed by the Management Commission. It is responsible for the preparation and execution of the professional and technical program; in that capacity, it also monitors the activities of regional branches, sections, and committees.
- The Audit Commission consists of a chair, known as the Internal Auditor, and four members elected by the members of the AGM. It is responsible for the evaluation of the performance of the ICA programs and of its

external and internal communications. It reports to the Executive Board and to the Annual General Meeting.

In addition to these three commissions, the work of the Executive Board is supported by a CITRA Bureau, composed of six elected members and a few ex-officio members to organize the annual International Conferences of the Round Table on Archives (CITRA) and to draw up the CITRA program.

The Secretariat is responsible for the day-to-day operation of ICA's organization, including communications with other ICA bodies and individual members, relations with partner organizations, and administration of ICA's governance meetings. It comprises a small staff based in Paris and is headed by the Secretary General, who acts as the organization's Executive Director.

Elected Officers

Since 2007, the top management of ICA is composed of a President and eight Vice-Presidents. Four Vice-Presidents are elected by the membership for Marketing and Promotion, Programme, CITRA, and Finances; the other four play that role by virtue of their particular function within ICA: host of the forthcoming congress, the chair of SPA, the representative of regional branches and the representative of sections. With the exception of the Vice-President of the CITRA, the elected officers are elected for a 2-year term, which may be renewed.

Budget

ICA has an annual budget of approximately €1,000,000, generated for the most part by dues from the members. The level of dues paid by national archival institutions is calculated on the basis of each country's gross national product as established by the International Monetary Fund. The dues of the associations are fixed according to the number of members. Part of the dues are allocated to the regional branches and the section; another portion provides the basis for the funding of projects approved by the Programme Commission. At the time of writing ICA has just started a review of the criteria used to calculate membership dues and the associated benefits.

ICA ACTIVITIES

Beyond the regular activities of ICA during the Congress, the CITRA and the publications, members are invited to submit projects which further the organization's objectives. The current Strategic Direction document includes six approved objectives, which provide the Programme Commission with a framework to make its decisions about projects submitted by members:

1. Raising awareness.
2. Influencing the development and use of new technologies.
3. Building capacity in the records and archives profession.
4. Strengthening the ICA network.
5. Improving the performance and accountability of ICA.
6. Building partnerships.

Congress

Every 4 years, in a different country, ICA holds an International Congress on Archives which can be attended by all archival professionals. The most recent congress was held in Kuala Lumpur in Malaysia in July 2008 on *Archives, Governance and Development*. The next one will take place in Brisbane, Australia, in 2012 on the theme of *Archives in a Digital Age*.

Previous Congresses presented a wide diversity of themes touching the multifaceted aspects of the profession.

- *1950 Paris*: Records management, micrography, private archives (mostly business archives), and bibliographies on archives.
- *1953 The Hague*: Terminology standardization, documentation, history of art and history museums, training, and public programs.
- *1956 Florence*: New buildings, archival appraisal, and private archives.
- *1960 Stockholm*: National archives, restoration, conservation, and photography; and economic and social history research.
- *1964 Brussels*: Modern methodology for the arrangement of archives.
- *1966 Washington, D.C. (Extraordinary Congress)*: Opening archives to research.
- *1968 Madrid*: Improved access to archives and microfilm policy; history of archives; the Salvage and Restoration of the Italian Archival Heritage after the Inundation of November 1966; and records management.
- *1972 Moscow*: Records management and state archives; new techniques in archives; finding aids for research; and support for archives in developing countries.
- *1976 Washington, D.C.*: The pre-archival revolution; the technological revolution; the revolution in access and use; and the geo-archival revolution.
- *1980 London*: The academic, practical, and popular use of archives; the ICA: its achievement and its future.
- *1984 Bonn*: The challenge to archives: growing responsibilities and limited resources.
- *1988 Paris*: New archival material.
- *1992 Montreal*: The profession of the archivist in the information age.

- *1996 Beijing*: Archives at the end of the century: taking stock and looking ahead.
- *2000 Seville*: The archives of the new millennium in the information society.
- *2004 Vienna*: Archives, memory, and knowledge: <http://www.wien2004.ica.org/fo/index.php>.

While congresses before 2004 mostly consisted of a series of plenary sessions presenting wide-ranging reports on the evolution of the profession or the various aspects of a general theme, the Vienna 2004 Congress and the 2008 Kuala Lumpur meeting were organized along more dynamic lines presenting 10–15 parallel sessions attended by smaller audiences and allowing more direct discussion between the speakers and the audience. About 1200 participants came to the 2008 Congress in Kuala Lumpur to see 326 speakers presenting at 53 workshops and 169 sessions. Topics ranged from audiovisual archiving to indigenous knowledge, and “green archives buildings.” ICA Commissions, Branches, and Sections used the opportunity to hold business meetings and the Annual General Assembly also took place. Many of the papers presented on that occasion are available on the Congress Web site (<http://www.kualalumpur2008.ica.org/en>). A selection of the papers will be published in the Congress *Proceedings*.

Conferences

In the intervening years of the Congresses, since 1954, there is an International Round Table Conference on Archives, also known as CITRA from the French acronym (Conférence Internationale de la Table Ronde des Archives). This is for representatives of national archive administrations, national professional associations, and the Chairs and secretaries of ICA sections. This Conference is accessible by invitation only and deals with strategic professional issues. The 41st CITRA was held in Quebec City in 2007. The papers are usually published in the *Proceedings*. The themes of the two more recent series of CITRA have been Archives and Society from 2001 to 2003 and Archives, Diversity, and Globalization for 2005–2008.

At the outset of Congresses and CITRA meetings, resolutions are usually adopted for the participants to implement in their respective countries.

Regional branches and sections regularly hold conferences and seminars.

Publications

The ICA Web site provides up-to-date information on the upcoming events and activities of ICA's bodies, branches, sections, and working groups (<http://www.ica.org>). It also offers a Resource Centre which contains hundreds of working documents, publications, and standards relevant to archival practice.

Comma, the ICA journal, is a merger of ICA publications *Archivum* (I–XLV), *Janus* (1983–1999), and *CITRA Proceedings*. It is edited in seven languages (Arabic, Chinese, English, French, German, Spanish, and Russian) and is usually published quarterly. Its main function is to disseminate research and discussion papers of interest to the membership of the organization, to the profession as a whole, and external readers. Printed on paper at the beginning, it moved in 2006 to a CD-ROM format. Three CD-ROMs have been published in 2006–2008. The 2008 Congress Proceedings will be published on paper as well as electronically, and it is possible that in the future paper publications will be reintroduced more generally.

Archivum was edited from 1951 to 2000 (no. 45) in five languages (English, French, German, Italian, and Spanish) and usually dealt with only one main subject. *Janus*, another ICA journal published between 1983 and 1999, was responsible for disseminating papers, reports, research work, and discussions of interest to the profession as a whole, mainly emanating from the activities of various ICA bodies. The *CITRA Proceedings* were printed as a separate publication from 1958 to 1999.

The newsletter *Flash* is published by ICA three times a year as a membership benefit. It conveys news on ICA activities and highlights current issues in archives. It can be downloaded from the ICA Web site.

The series *Studies* presents the works of ICA experts in a wide range of fields such as the management of electronic records, authenticity of electronic records, disaster prevention, control of radioactive waste information, and archival legal matters. The 19 *Studies* published are available on CD-ROM and can be downloaded from the ICA Web site.

Many sections and regional branches publish their own journal or a newsletter; most have their own Web site.

Projects

Since the 1990s, the emergence of information technologies has had a considerable impact on the archival profession, particularly for the creation, acquisition, processing, and dissemination of archives. The prevalence of computerized office work practices now requires the intervention of the archivist in the creation of records in the office. In order to ensure the preservation, authenticity, and integrity of records on a long-term basis, the archivist must be involved in all phases of the life of the record.

The new technological context has increased the needs for standardization and system interoperability, particularly in the area of *archival description*. Since the 1990s, ICA has adopted four professional standards (available on the ICA Web site):

- ICA-ISAD(G), the *International Standard for Archival Description* (General), provides guidance for the description of archival records.

- ICA-ISAAR (CPF), the *International Standard Archival Authority Record for Corporate Bodies, Persons, and Families*, provides guidance for the creation of authority record information about creators of archival materials.
- ICA-ISDF, the *International Standard for Describing Functions*, provides guidance for the description of functions of records creators.
- ICA-ISDIAH, the *International Standard for Describing Institutions with Archival Holdings*, provides guidance for the description of holders of archives.

Other projects include the creation of dedicated open source software to facilitate the creation of databases for archival repositories and the exchange of the descriptive data they contain. The beta version 1.0 of *Access to Memory* (A to M) (available at <http://ica-atom.org/>) was launched in 2008, during the Kuala Lumpur Congress to cater for small archival institutions and allow them to publish their finding aids on the Web. It is based on freely available, multilingual open source software.

Terminology has been a long-time concern of ICA since the end of the 1950s. Special glossaries are available for several areas, such as sigillography and preservation. The first general Dictionary of Archival Terminology was published in 1984. A new approach to defining the language of the profession was recently adopted through discussion of the project Archipaedia, which proposed to prepare and publish a multifaceted, multilingual, and multimedia online tool to favor better understanding of archival terminology and practices in as many languages and cultural groups as possible.

The ICA *Code of Ethics* for archivists was adopted by ICA in 1996. It establishes high standards of professional conduct for the archival profession by providing an ethical framework for the guidance of members of the profession.

COOPERATION WITH OTHER ORGANIZATIONS

When other organizations have better expertise than ICA members, archives professionals are encouraged to join those specific organizations, instead of setting up their own group within ICA. For example, members interested in Audiovisual Archives are invited to contact the CCAAA of which ICA is a founding member.

ICA works closely with intergovernmental and NGOs. Most of these organizations are active mainly or partly in the cultural heritage field and/or in information management, business administration or in development of third world countries.

ICA maintains its status as an NGO recognized by UNESCO, with whom it has a Framework Agreement covering areas of joint interest; it regularly participates, as observer, in the meetings of the Information for All Program and has representatives in the various bodies of the memory of the world program. It has consultative status with the Economic and Social Council (ECOSOC of the UN), the International Federation of Library Associations and Institutions (IFLA) and the International Organization for Standardization (ISO) as well as observer status with the World Intellectual Property Organization (WIPO).

Throughout its 60 years of existence, ICA has constantly adapted to new environments and the information revolution. Its network of archival professionals is unique and encompasses the whole world and all facets of society. Facing a constant increase of the uses of archives and the expectations of society, it looks forward with confidence to new opportunities while continuing to work on the ever present problems of insufficient financial and human resources. In order to achieve significant results and encourage solidarity between its members, ICA must find additional allies and marshal energies and talents for the benefit of all its members and to further the cause of archives throughout the world.

International Council on Knowledge Management (ICKM)

Franz Barachini

Business Innovation Consulting—Austria, Langenzersdorf, Austria

Abstract

The objective of this entry is to explore the fundamental nature of knowledge management by examining relevant definitions, concepts, instruments, and strategies. It also reports on the development of the International Council on Knowledge Management (ICKM). ICKM is an association located in Vienna. The homonymous conference started in 2004 in Singapore with the launch of the first international conference on knowledge management. The tension between practitioners and academia is neither new nor limited to the field of knowledge management. The ability to bring these communities together will not only bridge the gap between the two worlds but also create the environment needed for the development of any discipline.

INTRODUCTION

Peter F. Drucker^[1] was one of the first researchers to mention the term “knowledge worker.” Since then, several approaches have focused on knowledge management initiatives, all of them pursuing one goal, to leverage the performance of individuals, groups, or companies. Knowledge management is regarded as an interdisciplinary field involving tasks such as learning, innovation, intellectual capital (IC) reporting (human, structure, relationships), and organizational optimization. The main challenge is how to discover, create, capture, share, and utilize knowledge via (social) networks. Knowledge management is not only an IT challenge, but mostly consists of motivating people to share valuable information so that IC of companies can be improved. Bontis,^[2] Edvinsson and Malone,^[3] as well as Sveiby^[4] see IC as the “stock” of knowledge that exists in an organization at a particular point in time. A similar view is described by Nonaka and Takeuchi^[5] who defined knowledge management as managing the stock of knowledge in an organization as it flows over time. Managing this stock remains a challenge, as there is the need to socialize and codify intangible (tacit) knowledge.

There are several various theories of knowledge management. Bonifacio et al.^[6] characterize knowledge sharing and knowledge management as the process of creating, codifying, and disseminating knowledge. They claim that knowledge can be disseminated; however, this approach assumes the existence of an objective epistemology, so that all contextual, subjective, and social aspects of knowledge can be eliminated in favor of an objective and general codification. This is undoubtedly an interesting idea; however, individuals tend to interpret data

immediately after acquiring it. It seems clear that different knowledge can be produced from the same chunk of information contained in different brains, no matter how this information is codified.

It would seem therefore that only information can be disseminated and exchanged and not knowledge. This view is also supported by the school of autopoietic epistemology which states that knowledge is a private, personal matter which is intuitively and strongly linked to a person’s values and beliefs. Explicit knowledge is data and information that enable other people to create their own knowledge via a “structured coupling” process explained by Joia.^[7] There are techniques existing such as sharing knowledge through common experience, through storytelling or microarticles—for all these techniques, the basis is information flow based on text, speech, smell, optics (behavior), or tangibles. This information is then interpreted by our brain according to our context knowledge, previous experiences, instincts, and intuitions. The usage of the terms “knowledge sharing” and “knowledge management” in this entry therefore refers to information exchange processes and various individual interpretations of transferred data. Thus, knowledge is created purely through information transfer and successful or unsuccessful knowledge sharing is a consequence thereof. This point of view has been explained in depth by Barachini^[8] who asserts that knowledge management is performed in human brains only – all the rest is data and information management.

Scientists commonly recognize four types of knowledge:

1. Tangible and individual knowledge, characterized by fact knowledge
2. Tangible and collective knowledge, characterized by rules and written instructions

3. Intangible and individual knowledge, characterized by experience
4. Intangible and collective knowledge, characterized by hidden values and beliefs (society's unwritten laws)

As a result, there exists a distinct difference between tangible and intangible knowledge.

KNOWLEDGE MANAGEMENT CONCEPTS

Senge Approach

According to Peter Senge,^[9] learning organizations are organizations where people continually expand their capacity to create the results they desire, new and expansive patterns of thought are nurtured, collective aspiration is generated, and where learning takes place on an individual as well as collective level.

Managers can detect organizational learning disabilities by utilizing the following five principles:

- I. Personal Mastery: both life and work should be approached “as an artist would approach a work of art”
- II. Mental Models: deeply ingrained assumptions or mental images “that influence how we understand the world and how we take action”
- III. Building Shared Vision: when there is a genuine vision “people excel and learn, not because they are told to, but because they want to”
- IV. Team Learning: team members engaging in true dialogue without assumptions
- V. Systems Thinking: the integrative (fifth) discipline that fuses the other four into a coherent body of theory and practice

These five disciplines should be employed continuously in order to improve existing capacities. Since learning organization theories usually target the same approaches as that of knowledge management, there tends to be a close correlation between learning and managing knowledge.

Senge also mentions innovation management, which is the cornerstone of humankind. The success of innovation management heavily depends on the quality of IC. IC itself is characterized by human relationships, human knowledge, and structural aspects.

Nonaka/Takeuchi's Approach

Nonaka published the SECI model in 1991 (Fig. 1). His spiral model shows how to share tacit and individual knowledge with colleagues.^[5]

The first step, socialization, transfers tacit knowledge between individuals through observation, imitation, and practice. In the next step, externalization is triggered by dialogue or collective reflection and relies on analogy or

Fig. 1 The knowledge spiral.

metaphor to translate tacit knowledge into documents and procedures. In the third step, combination consequently reconfigures bodies of explicit knowledge through sorting, adding, combining, and categorizing processes and spreads it throughout an organization. Finally, internalization means the process of explicit knowledge transferred into individual tacit knowledge. Possibly, through a phenomenon that Nonaka calls the “knowledge spiral,” knowledge creation and sharing becomes part of the culture of an organization.

In 1997/1998, Tsoukas^[10] theorizes that tacit and explicit knowledge were not two separate forms of knowledge, but rather inseparable and necessary components of all knowledge. Nonaka followed with a slightly enhanced SECI model in 1998 called “Ba.” “Ba” is a convenient place where knowledge can be exchanged. Nonaka pointed out that knowledge is not only produced from individuals, but from interaction between individuals and the surrounding environment. Therefore, the more inspiring the “Ba,” the better the knowledge sharing results will be.

In 2011, Nonaka and Takeuchi^[11] coined the term phronetic leadership. For them, phronetic leadership means mastering the following management principles:

- I. Ability to make judgment on goodness
- II. Ability to create Ba
- III. Ability to see the reality as it is
- IV. Ability to articulate the essence
- V. Ability to exercise political power
- VI. Ability to foster phronesis on others

There is some parallelism between the observations of Senge, Drucker, and Nonaka. Phronetic leadership means pragmatic idealism that is not a contradiction in the eyes of Nonaka and Takeuchi. However, phronetic leadership might be harder to execute in western cultures than in the east because of cultural differences.

Probst/Raub/Romhardt's Approach

Probst^[12] merged a set of connected activities into a framework called the “building blocks of knowledge” (Fig. 2).

Fig. 2 Framework of the building blocks of knowledge.

This framework is often used to implement knowledge management initiatives in organizations. Senge's and Nonaka's approaches are more oriented toward sociology. Probst's approach is rather a technological one.

Knowledge goals point the way for strategic and operational knowledge management activities. The main focus is to improve competitiveness. Knowledge goals identify current skills and those which might be essential in the future.

Knowledge identification helps to establish whether internal and external knowledge is transparent. Knowledge acquisition has its focus on the external provision of knowledge. Knowledge development focuses on processes that generate new knowledge. Knowledge distribution deals with the transfer of knowledge inside a company.

Knowledge preservation memorizes valuable knowledge while ensuring suitable storage. Knowledge use is focused on the productive adoption of organizational knowledge.

The "knowledge measurement" building block is placed at the end of the process. In this block, the IC is analyzed and evaluated. This results in improvements such as better education, more intensive customer relations, or the need to invest into better infrastructure.

According to the feedback cycle, it is necessary to measure the "intellectual capital variables" in order to focus on target-oriented interventions. The problem is how to identify and measure these variables. Some variables such as fluctuation coefficients are easily measured while others such as tacit knowledge, which cannot be externalized by any of the methods mentioned, remain impossible to measure. Until recently, there was no commonly accepted standard for measuring IC.

INTELLECTUAL CAPITAL REPORTING

Intellectual capital consisting of structural, human, and relationship capital is part of each organization. Equipment,

infrastructure, intellectual property rights, procedures, and processes are regarded as structural capital. Skills and expertise of employees and management are parts of the human capital. The relationship between staff and external parties such as customers, business partners, friends, or teachers represents relationship capital.

Sveiby and Edvinsson^[4] are considered the fathers of IC reporting. They identified methods and as a consequence variables characterizing structural, human, and relationship capital. Similar to accounting balance sheets, measured variables are reported once a year. Skandia and Celemi were one of the first companies in Europe to experiment with IC reports. It is not possible however to map all the different variables into one single value so that they can easily be compared between companies. Barachini^[13] noted in his entry when he presented the business transaction theory that it is not possible to measure tacit individual knowledge since people do not offer knowledge (information) for free. He theorized that people employ "tit for tat" behavior during the information exchange process. This behavior is best explained by trading aspects of the modern portfolio theory. Taking the business transaction theory and the autopoiesis seriously, we can conclude that there will always be a part of knowledge which will remain undiscovered.

The main idea behind an IC report is that financial information reveals much about the past performance of an enterprise but says nothing about its future potential. An enterprise's future potential has much more to do with its IC. Creating transparency within the organization's IC will enable it to manage its intangible resources better, increase its staff's confidence and motivation, as well as impart greater certainty to investors and other stakeholders about its future earnings potential. Reflecting the importance of knowledge as an asset, the IC report outlines the knowledge goals of the company, its knowledge-based capital, its business processes, as well as its products and services.

Deductive Methods	Inductive Methods	
	Structural Model	Process Model
Tobin's Ratio	Skandia Navigator (Edvinsson)	Balanced Scorecard (Kaplan, Norton)
Return on Assets Methode-ROA	Intangible Asset Monitor (Sveiby)	IC-Index (Roos)
Return on Management (Strassmann)	IC-Rating (Edvinsson)	Danish Guideline
Calculated Intangible Value		Intellectual Capital Report (ARCS)
Financial Method of Intangible Assets Measurement-FiMIAM (Rodov, Lelliaert)		

Fig. 3 Selected methods for intellectual capital reports.

National and international accountancy rules increasingly regulate how IC is reported. There are more than 35 intangible asset-measuring models existing. These models basically differ in one aspect. One type of models use inductive methods, the others use deductive methods. Deductive methods evaluate IC by calculating functions expressing monetary values. Inductive methods are score-card oriented. Inductive methods are subdivided into structure- and process-oriented models (see a selection of methods in Fig. 3). Structure-oriented models classify IC into categories and attempt to systematically measure an organization's knowledge assets. Process-oriented models focus on coverage and description of knowledge flows.

Although a wide range of methods for measuring and reporting IC have been developed during the last decade, especially for internal managerial purposes, companies have been reluctant to implement them. Investors are reluctant to invest in IC because of its inherent high-risk nature. Since IC is one of the main drivers of value creation and growth, this negative investment bias is seen as harmful, particularly for research-intensive and innovative enterprises.^[14]

KNOWLEDGE MANAGEMENT INSTRUMENTS

On a formal level, instruments are tools, techniques, or methods. A complete list of all existing instruments of knowledge management would be beyond the scope of this entry. Following the popular framework from Probst (see Fig. 2), we can define at least one instrument per building block. Some of these instruments are supported by IT, web technologies, or social (soft)ware.

Building Block: Knowledge Measure

"Intellectual capital statement" represents coherences between organizational targets, business processes, IC, and organizational profit. One well-known framework used to measure IC is the Austrian Research Center's IC report. This report measures different indicators from structural, human, and relationship capital. Innovation indicators are also integrated (see Fig. 4).

The ARC IC report^[15] is an inductive process-oriented model developed in 1999. Currently, these types of models form the most common representation of IC reports. The German approach provides a similar more practicable model.

The logic of this model combines goals, IC, knowledge processes, and intangible results. The process of acquiring, applying, and exploiting knowledge starts with the definition of specific knowledge goals, which can be derived from the corporate strategy. Knowledge goals define areas where specific skills, structures, and relationships should be established or increased in order to ensure the implementation of a corporate strategy. Derived from these goals, the IC consisting of structural, human, and relational capital is exploited. These intangible resources serve as input for the knowledge production process, which in turn is manifested in the different types of projects or processes carried out in an organization.

The model provides a framework for its adaptation and adoption by other organizations. When applying this

Fig. 4 Structure of the ARC intellectual capital report.

model, organizations have to formulate explicitly the organizational goals relevant for the resources and processes.^[16]

Building Block: Knowledge Identification

Knowledge can be identified by knowledge or data miners. These are software programs that mine the web in order to identify useful chunks of information—a process known as “business intelligence.” Knowledge can also be discovered by a “knowledge café” where people join different tables in order to discuss various topics with various partners.^[16]

Building Block: Knowledge Acquisition

The simplest way to acquire knowledge is by reading a book, studying an encyclopedia, weblog, or communities of practice.

Building Block: Knowledge Development

Knowledge is developed through experience, trial, and error. This means that the practical application of acquired knowledge helps to develop further knowledge.

Building Block: Knowledge Distribution

Knowledge can be transferred by the telling of stories. Not only is the core message transmitted during this process but also all necessary background knowledge and semantics that are needed to understand the core message are relayed by dialogue.

Building Block: Knowledge Preservation

The brain is the body’s primary repository of knowledge. Other sources such as databases on the web, data marts, MySpace, YouTube, Facebook, and blogs represent information stores.

Building Block: Knowledge Use

The techniques mentioned in the other blocks are combined and used in organizational processes so that the performance of individuals or groups is enhanced.

Information sharing is the cornerstone of knowledge management. Existing IT, referred to as social ware, helps people to share information and collaborate in an optimal fashion. Knowledge management is the management of this information flow, getting the right information to the people who need it so that they can act on it in due time.

Today many companies are using social ware to optimize collaboration and to improve results. Cultural and social problems however may occur during the collaboration process.

INTERNATIONAL COUNCIL ON KNOWLEDGE MANAGEMENT

For knowledge management as a discipline to succeed, a specialized body of knowledge, theory, hypotheses, observations, and problems must be formulated, tested, and applied. As the early activities in knowledge management were mainly dominated by practitioners and commercial activities, academicians and researchers saw the need for building the foundation for sustainable and solid research and development in this area. This effort started when a number of universities around the world started to offer graduate degrees in knowledge management. Given the interdisciplinary nature of knowledge management, it is also important to bring people from different but related disciplines to contribute to the development of the knowledge management profession. The absence of a scholarly professional body with the goal of advancing knowledge management as a discipline was the main motive for the formation of the International Council on Knowledge Management (ICKM). ICKM is an association that is based in Vienna.

The first ICKM conference started in 2004 in Singapore with the objectives of promoting knowledge management practices as well as bringing researchers, academics, and practitioners together to exchange ideas and share information. Since then, the conference became a great success and continues to move from one continent to another. Unfortunately, ICKM is not a trademarked word. Other organizations are using this name to arrange conferences with similar content.

ICKM council and ICKM series of conference came about as a result of one-person effort that started back in 1998. Dr. Suliman Hawamdeh who is currently a professor at the University of Texas founded the Information and Knowledge Management Society (iKMS), the organization behind the organization of the first ICKM conference in Singapore 2004. Dr. Hawamdeh was the founding director of the knowledge management program at Nanyang Technological University in Singapore and he is the editor in chief of the first refereed journal on knowledge management—the Journal of the Information and Knowledge Management. His vision is to create a scholarly and professional body with an international presence to promote and advance the iKMS profession.

While iKMS remained as a local Singapore-based KM association, it continues to support the ICKM council and the ICKM series of conferences. Professor Hawamdeh, the founding chair of the International Conference on Knowledge Management, continues the general chair duties and delegated the organization aspects to local organizers who manage the event as a nonprofit event with the objective of bridging the gap between academia and practitioners. ICKM is a platform for leading international forum for researchers and practitioners who come together to exchange ideas, share research findings, and network. Although all participants may openly and freely present

ideas and theories, the proceeding, which is published as a book and part of the book series Innovation and Knowledge Management and edited by professor Hawamdeh, is limited to peer-reviewed papers, an approach that should guarantee high scientific quality with practical implications. Key individuals who played an important role in the successful organization of ICKM conferences so far include Patrick Lambe, Martyn Laycok, Franz Barachini, Sam Chu, Waltraut Ritter, and Adeline du Toit.

CONCLUSION AND FUTURE TRENDS

We have presented three well-known concepts of knowledge management and discussed the different perspectives of knowledge management and IC reporting. Furthermore, we have presented instruments that are subject of investigation in conferences as the ICKM.

Knowledge management itself can be seen as bringing the right knowledge to the right people in due time so that IC can be improved. The problem is how to motivate people to share information. Appropriate rewarding schemas do exist, but they are not widely used in companies because it is too difficult to measure the value of information and the value of individual contributions. Much more research is needed in rewarding schemas.

Other obstacles for knowledge sharing are the divide between rich and poor and the divide between educated and uneducated. Cultural differences also hamper knowledge sharing. We are convinced that there is a need to develop performance measurements for corporate social responsibility and to combine this with shareholder value. Substantial research is needed in this area and we hope that the international conference on knowledge management will go a long way to stimulate such objectives.

If we accept knowledge as being a very private personal affair, then we recommend concentrating more research efforts toward neuroscience and neurobiology. In particular, the influence of emotions on knowledge sharing seems to be evident.

International Federation of Library Associations and Institutions, The Hague, the Netherlands

Abstract

The International Federation of Library Associations and Institutions (IFLA) is the leading international body representing the interests of library and information services, their staffs, and users. The International Federation of Library Associations and Institutions is an independent, nongovernmental, not-for-profit organization, registered in The Hague as an association under the law of the Netherlands. Founded at an international congress in Edinburgh, Scotland, in 1927, it has become the global voice of the library and information profession.

INTRODUCTION

The International Federation of Library Associations and Institutions (IFLA) is the leading international body representing the interests of library and information services, their staffs, and users. The International Federation of Library Associations and Institutions is an independent, nongovernmental, not-for-profit organization. It was founded at an international congress in Edinburgh, Scotland, in 1927, as the International Federation of Library Associations, a federation of national library associations. Prior to World War II the orientation of the association was strongly European; eight of the nine presidents who served during IFLA's first 50 years were from Europe, and the majority of IFLA congresses were held in European cities. After the war, IFLA's membership expanded and in the 1970s special efforts were made to expand the membership to developing countries. The first of a series of presession seminars for librarians from developing countries was held in 1971. In 1976 a Division of Regional Activities, comprising three regional sections, for Africa, Asia and Oceania, and Latin America and the Caribbean, was established to serve members in the developing regions, where regional offices were subsequently set up. IFLA's first conference outside Europe and North America was held in Manila, the Philippines, in 1980. IFLA's first President from Africa, Kay Raseroka, from Botswana, served from 2003 to 2005;

the second, Ellen Tise, from South Africa, was elected to serve from 2009 to 2011.

In 1976 IFLA extended membership to libraries and related institutions and changed its name by adding "and Institutions," but left its well-known acronym unchanged. During the past three decades, IFLA has become the global voice of the library and information profession, and library leaders from many countries have served as president (see Appendix A).

MISSION

The statutes of IFLA (its constitution) state that the purposes of the federation shall be to: promote high standards of delivery of library and information services; encourage widespread understanding of the value and importance of high-quality library and information services in the private, public, and voluntary sectors; and represent the interests of members throughout the world. IFLA's mission, therefore, is to promote high standards of service by issuing guidelines to best practice and standards of provision, through international advocacy to persuade decision makers and opinion formers of the importance and relevance of libraries in the digital age, and to work for an estimated 690,000 librarians and information workers worldwide.

CORE VALUES

The statutes also state IFLA's core values:

- The endorsement of the principles of freedom of access to information, ideas, and works of imagination, and freedom of expression embodied in Article 19 of the Universal Declaration of Human Rights.
- The belief that people, communities, and organizations need universal and equitable access to information, ideas, and works of imagination for their social, educational, cultural, democratic, and economic well-being.
- The conviction that delivery of high-quality library and information services helps guarantee that access.
- The commitment to enable all members of the federation to engage in, and benefit from, its activities without regard to citizenship, disability, ethnic origin, gender, geographical location, language, political philosophy, race, or religion.

These represent values and beliefs but also, especially in paragraph (d), ambitious aspirations. The mission and the core values form the basis of the federation's worldwide activities.

MEMBERSHIP

The federation is primarily an organization of members, relying upon them both for the bulk of its income and most of its professional input. There are two main categories of voting members: national association members and institutional members. National associations of library and information professionals, of library and information services, and of educational and research institutes within the broad field of library and information science, are enrolled as national association members. Institutional membership is designed for individual library and information services and all kinds of other organizations within the library and information sector. In addition, international organizations within the federation's sphere of interest may join as international association members. In 2008, there were 1224 voting members from 139 countries. Together, these associations and institutions represent the vast majority of the world's librarians and other library staff. Voting members are entitled to nominate and vote for candidates for the post of IFLA president and for places on the federation's governing board.

Individual practitioners and students in the field of library and information services may join as personal affiliates and student affiliates, respectively. They do not have voting rights, but they are able to nominate and vote for places on the standing committees of the professional sections. They provide invaluable contributions to the work of the federation, by serving on those committees and by contributing to the professional programs. In 2008 there

were more than 300 personal and student affiliates in membership. National association members pay membership fees according to a graduated scale, based on the size of their operating expenditure. This helps ensure a reasonably equitable scale of fees.

For institutional members there is a system of differentiated fees based on the UNESCO scale of assessment. Personal affiliates pay a flat fee calculated so that it covers the expenses of administration and the benefits such as publications. For student affiliates there is a lower rate.

CORPORATE PARTNERS

The IFLA corporate partners' scheme enables a wide variety of companies in the library and information industry to have regular and direct contact in a variety of ways with the international library community. In return for financial and "in-kind" support, they receive a wide range of benefits, which may be negotiated on a flexible basis to suit individual needs. Corporate partners include publishers, subscription agents, software producers, and distributors of library furniture and equipment. Long-term relationships have been developed with a number of companies. For example, OCLC of Dublin, Ohio, U.S.A., offers the Jay Jordan IFLA/OCLC Early Career Development Fellowship Program. Every year up to six fellows from countries with developing economies travel to OCLC headquarters for 4 weeks to participate in an intensive program of lectures, seminars, and mentoring. They also visit a number of libraries and relevant organizations in North America, the Netherlands (where they visit IFLA Headquarters), and Germany. Depending on the level of financial support, companies are listed as Gold, Silver, or Bronze Corporate Partners.

RELATIONS WITH OTHER BODIES

Over the years, IFLA has established good working relations with a variety of international organizations whose interests, at least partly, coincide with those of IFLA. This provides an opportunity for regular exchange of information, formal representation at meetings and, in some cases, the award of grants, the mutual approval of statements, and other initiatives. For example, IFLA holds

- Formal associate status with UNESCO.
- Observer status with the United Nations.
- Associate status with the International Council of Scientific Unions (ICSU).
- Observer status with the World Intellectual Property Organization (WIPO).
- Observer status with the International Organization for Standardization (ISO).
- Observer status with the World Trade Organization (WTO).

UNESCO formally approved

- The Public Library Manifesto, a document summarizing the aims and key missions of public libraries with the role to serve as a reference for anyone who can contribute to the progress of public libraries throughout the world.^[1]
- The School Library Manifesto, which argues that school library services are so vital that they should be provided equally to all members of the school community, regardless of age, race, gender, religion, nationality, language, and professional or social status. The IFLA/UNESCO School Library Manifesto urges governments, through their ministries responsible for education, to develop strategies, policies, and plans that implement the principles of this Manifesto.^[2]
- The Internet Manifesto, proclaiming that unhindered access to information is essential to freedom, equality, global understanding, and peace.^[3]

All of these documents were drafted by IFLA sections. The common role of these manifestos is to advise and influence local, regional, and national governmental bodies in matters of library development. Funding has been received from UNESCO and other sources to distribute and promote the manifestos around the world. Guidelines for the provision of both public libraries and school libraries have been developed to supplement the manifestos and to help promote higher standards of service in these sectors. More recently the development of a set of IFLA/UNESCO Internet Manifesto Guidelines was funded by UNESCO and the Swedish International Development Cooperation Agency (Sida), and a series of workshops has been held in various parts of the world to promote their implementation.

The federation has offered consultative status to a number of nongovernmental organizations (NGOs), whose interests coincide with those of IFLA. This is often on the basis of mutual recognition. These arrangements include the International Publishers Association (IPA), the International Council on Archives (ICA), and the International Council for Scientific and Technical Information (ICSTI). This status facilitates the exchange of documents and mutual representation at each other's congresses. In some cases it has resulted in more tangible and practical outcomes. The IFLA and the IPA have, for example, set up the IFLA/IPA Steering Group to examine issues of mutual interest such as metadata, the legal deposit of electronic materials, and digital object identifiers.

In 1996 IFLA also collaborated with other NGOs to found the International Committee of the Blue Shield (ICBS) whose mission is to collect and disseminate information and to coordinate action in emergency situations where cultural heritage is threatened. The name was chosen because the 1954 Hague Convention for the Protection of Property in the Event of Armed Conflict specified use

of the blue shield for marking cultural sites to give them protection from attack in the event of war. In addition to IFLA, the NGOs within the ICBS are the International Council on Archives (ICA); the International Council of Museums (ICOM); and the International Council on Monuments and Sites (ICOMOS). In 2005 the Coordinating Committee of Audiovisual Archives Associations (CCAAA) joined ICBS. These international NGOs have joined together to provide the concerned authorities and professionals with expertise and guidance in cases of armed conflict and natural disasters that affect cultural heritage. They are also working together to organize risk preparedness at an international level and encourage its development at a local level. By 2008 national Blue Shield committees had been set up in 12 countries: Australia, Belgium, Benin, Brazil, Czech Republic, France, Italy, Former Yugoslav Republic of Macedonia, the Netherlands, Norway, Poland, and the United Kingdom; plans were afoot to set up such committees in a number of other countries.

THE IFLA WORLD LIBRARY AND INFORMATION CONGRESS

IFLA is clearly much more than just a congress. Nevertheless, IFLA's annual World Library and Information Congress (known until 2003 as the IFLA General Congress and Council) is its flagship event. At a gathering held in a different city each year, upward of 3000 delegates gather to exchange experience, debate professional issues, see the latest products of the information industry, conduct the business of IFLA, learn about the library and information infrastructure of the host country and to experience its culture. An important side benefit of attending the IFLA congress is the ability to renew and expand professional friendships from across the world. Every year IFLA's Governing Board selects the region in which the congress is to be held 3 years hence. A feasibility study is conducted by IFLA's professional conference organizer (PCO) and a shortlist of suitable venues in that region is drawn up. From these the Governing Board selects the winning city on the basis of criteria that include the geographic spread of the congress; the congress and exhibition facilities available; logistics, including ease of transportation and the availability of hotels in all price ranges; support from the local profession; and support from the government and other agencies. Each congress is arranged by a four-way partnership consisting of IFLA, an IFLA-controlled limited liability company based in the United Kingdom, the PCO, and a National Committee.

Each congress has a distinctive theme to which the various sessions, including plenary sessions, guest lectures open sessions, and workshops are expected to contribute. In recent years the IFLA congresses have been held in the following venues with the following congress themes:

- 2004, Buenos Aires, “Libraries: Tools for Education and Development.”
- 2005, Oslo, “Libraries—A voyage of discovery.”
- 2006, Seoul, “Libraries: Dynamic Engines for the Knowledge and Information Society.”
- 2007, Durban, “Libraries for the future: Progress, Development and Partnerships.”
- 2008, Québec City, “Libraries without borders: Navigating towards global understanding.”

In 2009, the IFLA congress will take place in Milan with general theme “Libraries create futures: Building on cultural heritage” and in 2010 in Gothenburg with theme “Engaging, Embracing, Empowering.” The 2011 congress will be held in San Juan, Puerto Rico, with a theme still to be announced.

A substantial trade and technical exhibition is arranged during the congress. The number of exhibiting companies and organizations usually exceeds 100. International Federation of Library Associations and Institutions Sections and other professional groups often arrange specialist workshops or seminars immediately preceding or following the congress. The venue for such satellite events is often in the same city as the congress itself or in some other location in the region.

Congress hosts sometimes link their own congress with the IFLA event in order to strengthen national participation. Other national, regional, or specialist professional groups often take the opportunity to economize on their members’ travel costs by arranging their own regular meetings in connection with an IFLA congress, which many of their members could be expected to attend. The IFLA congress often tends to have an invigorating effect on the profession in that country.

The congress is usually held in the third or fourth week of August. The congress itself lasts 5 days, but it is preceded and followed by business meetings of the Governing Board, its committees, and the committees of IFLA’s professional units. For members of these bodies the event may last up to 9 days. Starting on Sunday afternoon and continuing until Thursday morning there is a full program of guest lectures, professional sessions, and poster sessions. Around 400 papers on a wide spectrum of topics are presented in nearly 100 professional program sessions that are scheduled in six parallel slots, at two of which simultaneous interpretation is offered in IFLA’s seven languages. Around 100 posters are also presented in seven languages. Library tours offer participants the opportunity to visit libraries in the host city and other cities nearby. Receptions and cultural performances are held during the evenings. Embassies often host receptions for their own nationals and invited guests. International Federation of Library Associations and Institutions has a close relationship with the Conference of Directors of National Libraries (CDNL), an independent body, which holds its annual meeting during the congress week.

Building on the initiative of Denmark in 1997, most of IFLA’s congress hosts have established special funds to support participants from developing countries. A variety of congress participation grants, with varying eligibility requirements, are on offer. These are usually announced on IFLA’s Web site 6–8 months before the relevant congress.

In addition to the annual congress a wide range of professional meetings, seminars, and workshops are held around the world by IFLA’s professional units and core activities. Two other regular major international conferences are held under the auspices of IFLA: the five-yearly International Congress of Medical Librarians (ICML) will hold its 2009 congress in Brisbane in July 2009, and the biennial International Conference on Interlending and Document Supply (ILDS) will convene in Hanover, Germany, in October 2009.

GOVERNANCE

The governing structure of IFLA was revised in 2008, when revised Statutes and Rules of Procedure (regulations) were adopted. While the essential structure remained largely unchanged, greater flexibility was achieved by moving detailed provisions concerning professional units such as division and sections from the Statutes to the Rules of Procedure.

A description of the structure which will be in place from 2009 follows (see Fig. 1).

President

The president is the chief representative of IFLA and is expected to provide it with professional leadership. Among the formal duties of the president are the chairing of the meetings of the General Assembly and the Governing Board. The President is elected by the total voting membership by postal ballot and first serves a term of 2 years as president-elect, followed by 2 years as president. The president may serve for only one term. See Appendix A for a list of all past presidents.

General Assembly

The General Assembly, known until 2008 as the Council, is the highest organ of IFLA. It determines its policies and priorities. The voting members in good standing (that is, those who have paid their membership fees in full) constitute the General Assembly, which meets annually during the congress. Although voting in elections is by postal ballot, under Dutch laws decisions of the General Assembly have to be taken at these meetings. However, non-binding consultations are held by postal ballot on important issues. Voting members not able to be directly represented at a General Assembly meeting may arrange to have their vote

Fig. 1 IFLA organization chart.

exercised by proxy. Personal affiliates of the federation may attend the General Assembly as observers, but may not vote. Representatives of other organizations and other persons may be invited to attend as nonvoting observers. Observers may speak at General Assembly meetings at the invitation of the chair or with the permission of the chair. The International Federation of Library Associations and Institutions has a system of vote allocations which ensures that national association members have a majority vote in the General Assembly. At present, institutional members have one vote each, while international association members have five. National association members have an allocation ranging between 8 and 40, according to the membership fees they pay.

Governing Board

Over 1200 voting members are entitled to attend and vote at General Assembly meetings and to take part in postal ballots. The statutes, therefore, provide for a Governing Board of more manageable size to be responsible for the managerial and professional direction of the federation, within guidelines approved by the General Assembly. The Governing Board consists of: the president; the president-elect; ten members elected by postal and/or electronic ballot; the members of the Professional Committee, the chair of the Management of Library Associations Section and up to three co-opted board members. The Governing Board meets at least twice a year, once at the time and place of the annual congress. Other business may be conducted by post and electronic mail. The statutes provide for an Executive Committee with delegated executive responsibility to oversee the direction of the federation between meetings of the Governing Board. The Governing Board has the power to establish other committees.

Professional Committee

The Statutes provide for a Professional Committee that is responsible for coordinating the work of all the units within the federation responsible for professional activities, policies, and programs. This committee consists of a separately elected chair, a representative, usually the chair, of each of the five divisions of IFLA, together with three members of the Governing Board, elected by that board. The Professional Committee meets at least twice a year, once at the time and place of the general congress.

PROFESSIONAL UNITS

Much of the professional work of the federation is carried out by professional units known as sections and (from 2009) special interest groups, which replace the units formerly known as discussion groups. These are coordinated by divisions, which are in turn represented on the Professional Committee.

Divisions

The Governing Board is responsible for establishing a series of divisions, whose role is to promote and coordinate the work of IFLA in broad categories representing the aspects of the interests of the profession. Divisions coordinate the work of sections, special interest groups (SIGs) and core activities. However, the routine administrative work formerly carried out by divisions was reduced in 2008 and in terms of the new statutes their former coordinating boards, consisting of the chairs and secretaries of the sections belonging to the division, have been replaced by leadership forums. The chair of each division has a seat

on the Professional Committee. As from 2008 there are five divisions: Library Types, Library Collections, Library Services, Support for the Profession, and Regions

Sections

Sections are the primary focus for the federation's work; they are grouped as follows in the five divisions:

- Library Types (for example, academic and research libraries, law libraries, biosciences libraries).
- Library Collections (for example, government information and official publications, rare books and manuscripts, newspapers).
- Library Services (for example, reference and information services, library services to multicultural populations).
- Support for the Profession (for example, management and marketing, education and training, library buildings, and equipment).
- Regions (Africa, Asia and Oceania, Latin America, and the Caribbean).

All IFLA members are entitled to register for sections of their own choice. Once registered, voting members have the right to nominate and elect specialists to the standing committee of the sections for which they are registered. The standing committee is the key group of professionals who develop and monitor the program of work of their section and prepare its sessions at the annual congress. Sections receive annual subventions from central funds with the approval of the Professional Committee. They are also able to apply for additional funds to carry out specific projects, such as the preparation of best practice guidelines, the compilation of a directory, or the conduct of a survey. Often such projects are published in the IFLA publications series. Each section publishes a newsletter for its members. They are usually published twice a year and may be made available to other interested persons. The contents are also usually published on IFLA's Web site. Some of the newsletters contain substantial professional articles. Most sections also have an electronic mailing list. There are, as of 2008, 45 sections. The Professional Committee has the power to approve a proposal to create a new section or to disband an existing section.

Special Interest Groups

In 2001 IFLA's Round Tables were disbanded, the relevant groups becoming either sections or discussion groups. Starting in 2009 the latter will be replaced by special interest groups (SIGs). SIGs are less formal groupings, which cater for aspects of library and information services that do not require the establishment of a section because they deal with matters that may be of highly specialized or potentially short-lived interest. SIGs are normally linked to

a sponsoring section. To establish a SIG, interested members petition a relevant section. If sufficient members express interest, the sponsoring section agrees, and certain criteria are met, the Professional Committee approves the establishment of the SIG. As of 2008 IFLA had eight discussion groups that were expected to become SIGs. They include discussion groups on such topics as e-learning, agricultural libraries, quality issues in libraries, and new professionals. A substantial number of other groups was waiting to submit petitions as well. Although SIGs do not receive regular funding from central sources, they are eligible to apply for finance to carry out projects. They run sessions as part of the general congress. Most also have an e-mail discussion list.

Regional Activities

Three regional sections—Africa, Asia and Oceania, and Latin America and the Caribbean—make up the Division of Regional Activities. All IFLA members located in these regions are automatically registered for the respective regional sections free of charge, in addition to other sections for which they may choose to register. The three regional sections are concerned with all aspects of library and information services in their regions. They promote IFLA activities and work closely with all IFLA's professional units, IFLA core programs, and with the respective IFLA regional offices.

Core Activities

Between 1973 and 1997 IFLA established six core programs to provide leadership and a focal point for work on strategic issues of common concern to library and information services around the world. In the following decade financial pressures and management changes in several of the libraries hosting core programs forced a rethinking of these programs. They were renamed core activities, the new designation implying less permanence and a greater openness to change than before.

Several of the older programs had continued for some years and were thought to have achieved as much as they could. Consequently three were closed down during 2001–2003: Universal Dataflow and Telecommunications (UDT), Universal Bibliographic Control and International MARC (UBCIM), and Universal Availability of Publications (UAP), with the Office for International Lending. Responsibility for the international interlending vouchers scheme was taken over by IFLA Headquarters.

Universal Bibliographic Control and International MARC was replaced by a new group formed by a partnership between IFLA and the Conference of Directors of National Libraries (CDNL) to form an Alliance for Bibliographic Standards (ICABS), subsequently renamed IFLA-CDNL Alliance for Digital Strategies (ICADS).

The National Library of Portugal took over the UBCIM's UNIMARC activities.

With the exception of the Advancement of Librarianship in the Third World Program (ALP), hosted in the University Library of the University of Uppsala, Sweden, the core programs were hosted and supported by major national libraries, which provide staff, accommodation, and support services. Such support in kind is supplemented by grants-in-aid from library associations, institutions, and aid agencies, particularly in the Nordic countries, as well as by project funding from foundations and aid agencies. The International Federation of Library Associations and Institutions itself provides on-going support from its Core Activities Fund, to which most major national libraries contribute. Since 2004 IFLA has had six core activities, which are described below.

Action for Development through Libraries (ALP) core activity

ALP was established in 1986 as the Advancement of Librarianship in the Third World Program. In 2004 it was renamed Action for Development through Libraries, but it retains its acronym and remains at the University Library of Uppsala, Sweden. The mission of ALP is to further the library profession, library institutions, and library and information services in the developing countries of Africa, Asia and Oceania, and Latin America and the Caribbean. Its goals are to assist in continuing education and training; to support the work of library associations; to promote the establishment and development of library and information services to the general public, including the promotion of literacy; and to introduce new technology into library services. ALP also acts as a catalyst within IFLA for the federation's activities in developing countries. Cooperation with a wide range of organizations within and outside the federation is a feature of ALP. ALP works through a planned program of activities in close cooperation between its office at Uppsala University, Sweden, IFLA's Regional Offices, the Division for Regional Activities, the three Regional Sections, and other partners. Activities include scholarships and attachment programs, conferences, seminars and training workshops, pilot projects, publications, and databases. ALP also administers grants from various foundations and aid agencies to enable librarians from developing countries to attend the IFLA general congress. During the period 2005–2009 ALP received substantial project funding from the Swedish International Development Cooperation Agency (Sida). A major contribution in-kind is made by Uppsala University, which hosts the ALP Office. Recent examples of projects undertaken by ALP are a Workshop entitled "Model of community information services in indigenous villages," held in Bolivia, Ecuador and Peru in May–June 2005, and an "International workshop on Information Literacy," held in Bangladesh in 2008.

Preservation and Conservation (PAC) core activity

PAC was established in 1986 with the mission to encourage best practice in preservation and conservation of library material internationally by publishing guidelines to good practice, running practical workshops, and persuading decision makers to give higher priority to preservation and conservation issues. Unlike the other IFLA Core Programs, PAC was established in a decentralized way with an international center and a series of regional centers responsible for their own policies and priorities.

The International Center has been hosted by the Bibliothèque nationale de France in Paris since 1992 and there are regional centers respectively located in Washington (Library of Congress), Caracas (Biblioteca Nacional de Venezuela), Rio de Janeiro (Fundação Biblioteca Nacional de Brasil), Santiago (Biblioteca Nacional de Chile), Port of Spain (National Library and Information System Authority of Trinidad and Tobago), Porto-Novo (National Library of Benin), Cape Town (UCT Libraries, South Africa), Tokyo (National Diet Library), Canberra (National Library of Australia), Moscow (Library for Foreign Literature) and Almaty (National Library of Kazakhstan). The International Center in Paris (Bibliothèque nationale de France) acts as the Regional Center for Western Europe, Middle East and Africa. Recent projects undertaken by PAC include an International Conference on "Newspapers Collection Management: Printed and Digital Challenges" held in Santiago, Chile, in April 2007 and the publication of "IFLA Disaster Preparedness and Planning: A Brief Manual" by John McIlwaine, in 2006.^[4]

The roles of the centers are defined in a working agreement between IFLA and each center. Each center is, however, independent and acts according to the needs identified in its region. Together these centers form an international network. The directors meet annually for working sessions to coordinate the programs. Apart from the substantial contributions in-kind provided by the host libraries, funding is received from IFLA's Core Activities Fund, project finances from agencies such as UNESCO, and the sale of publications. PAC publishes *International Preservation News*, which appears three times a year.

Committee on Copyright and Other Legal Matters

The Committee on Copyright and Other Legal Matters (CLM) was established in 1996 to advise IFLA with respect to copyright and intellectual property, economic barriers to the acquisition and use of library materials, trade agreements affecting library services, disputed claims of ownership of library materials, authenticity of electronic texts, subscriptions and license agreements, and other legal matters of international significance to libraries and librarianship. The Committee operates through a committee which is representative of all regions of the world

and includes invited resource persons. It cooperates with several important partner organizations with complementary missions: Electronic Information for Libraries (eIFL), the European Bureau of Library, Information and Documentation Associations (EBLIDA), the World Blind Union, and the (U.S.) Library Copyright Alliance.

The Committee's focus is on international activities and in recent years CLM has participated actively in meetings of the World Trade Organization (WTO) regarding the General Agreement on Trade in Services (GATS) and the Agreement on Trade Related Aspects of Intellectual Property Rights (TRIPS); at UNESCO, including meetings during 2001–2005 on the UNESCO Convention on the Protection and Promotion of the Diversity of Cultural Contents and Artistic Expressions (popularly known as the Convention on Cultural Diversity); and at the World Intellectual Property Organization (WIPO). Through written and oral interventions, collaboration with like-minded NGOs, and advocacy with representatives from member states, CLM achieved some notable successes for libraries in respect of such issues as the WIPO development agenda, traditional knowledge, and limitations and exceptions for libraries and for the visually impaired. The latter issue is an example of CLM's collaborative work: collaborating with IFLA's Libraries for the Blind Section, IFLA's national association members, and the World Blind Union (WBU) in persuading national governments to add to their national copyright laws provisions from WIPO's model copyright law that would improve access to information for print-disabled people. An important CLM activity has been raising awareness in the library community and providing guidance to the profession on issues with implications for library collections and services, for example, on copyright of digital resources.

Committee on Freedom of Access to Information and Freedom of Expression

The Committee on Freedom of Access to Information and Freedom of Expression (FAIFE) promotes freedom of information through libraries to improve the quality of life of individuals and groups. It tackles censorship of library materials; ideological, economic, political, or religious pressures resulting in limitations on access to information in libraries; and restrictions on librarians and other information specialists who provide reference and other information services. FAIFE empowers librarians and library users by promoting intercultural and interreligious tolerance, extending access to health information and combating corruption.

FAIFE attempts to monitor the state of intellectual freedom within the library community worldwide. In doing so it depends on networking and partnerships. For example, FAIFE is a member of various international intellectual freedom bodies such as the International Freedom of Expression Exchange (IFEX). In response to

violations of freedom of expression, and only once these have been confirmed from independent sources, IFLA may issue press statements, which can be found on the IFLA Web site.

Research and publications form an important part of FAIFE's advocacy work. Since 2001, FAIFE has annually published a unique *World Report* based on international data collection that provides an overview of how libraries around the world are tackling barriers to freedom of access to information and freedom of expression. Seven reports have appeared to date and the most recent, the IFLA/FAIFE World Report 2007, is entitled *Access to Libraries and Information: Towards a Fairer World*.^[5]

FAIFE supports IFLA policy development by conducting research and drafting policy statements and guidelines on various aspects of intellectual freedom in libraries. A good example is the *Internet Manifesto*, which has thus far been translated into 19 languages, and the complementary *IFLA/UNESCO Internet Manifesto Guidelines* funded by UNESCO.^[6] These have been workshopped and promoted in various parts of the world. This illustrates a recent shift in FAIFE's work: there is now more emphasis on raising the awareness of the library profession of freedom of information issues through educational seminars, workshops, and professional programs at IFLA's annual congresses and less on reacting to violations.

IFLA-CDNL Alliance for Digital Strategies

In 2003, when the UBCIM core activity was terminated, the National Library of Australia, the Library of Congress, the British Library, the Koninklijke Bibliotheek, and the Deutsche Nationalbibliothek agreed to participate in a joint alliance together with the Biblioteca Nacional de Portugal (responsible for the UNIMARC core activity), IFLA and the Conference of Directors of National Libraries (CDNL) to assure ongoing coordination, communication, and support for key activities in the areas of bibliographic and resource control for all types of resources and related format and protocol standards. This new alliance was known as the IFLA-CDNL Alliance for Bibliographic Standards (ICABS). In 2008 ICABS changed its name to ICADS, IFLA-CDNL Alliance for Digital Strategies, signaling a shift of emphasis away from "legacy systems" of bibliographic control such as the International Standard Bibliographic Descriptions (ISDN), toward digital library development and management, with three broad themes: creating and building digital collections (including digitization, Web archiving, and digital archiving); managing digital collections (including digital ingest, storage, and preservation); and accessing digital collections (digital resource discovery and digital rights management). IFLA-CDNL Alliance for Digital Strategies works through a coordinated Web presence based on the Preserving Access to Digital Information (PADI) site of the National Library of Australia, and

though an annual program of events at the IFLA congress. The Secretariat of ICADS is currently maintained by the British Library.

UNIMARC

The Universal MARC (UNIMARC) standard format for machine-readable catalogs was originally created by IFLA to facilitate the international exchange of bibliographic data. It was developed and promoted by the former UBCIM core activity under the supervision of the Permanent UNIMARC Committee (PUC), which had been formed in 1991. When UBCIM was terminated in 2003, the IFLA UNIMARC Core Activity was established with the responsibility for the maintenance and development of the UNIMARC format.

The purpose of the UNIMARC core activity is to coordinate activities aimed at the development, maintenance, and promotion of the UNIMARC format, now a set of four formats, Bibliographic, Authorities, Classification, and Holdings and related documentation, through the Permanent UNIMARC Committee. In this connection it cooperates with relevant professional units of IFLA as well as with the International Organization for Standardization's Committee ISO TC46, the international agencies for standard numbers such as ISBN and ISSN, and various other international bodies. The IFLA UNIMARC core activity is hosted by the National Library of Portugal in Lisbon.

ADVOCACY

IFLA has a long history of advocacy in the field of library and information services with a focus on promoting the development of librarianship and library services worldwide through interlinked activities relating to international library cooperation, the development and dissemination of best professional practice and stimulating and assisting library development in developing countries. The emergence of the CLM and FAIFE core activities heralded a stronger advocacy focus, on the themes of Equity (fair and sustainable legal and economic relationships between the creators, intermediaries and users of information) and Freedom (freedom of access to information and freedom of expression), respectively. IFLA's advocacy became more prominent in the buildup to the World Summit on the Information Society (WSIS) in 2003–2005, with an emphasis on a third theme: Inclusion: the role of the library in the Information Society and the role of the library as an agency of social inclusion. The latter theme was emphasized in various events and actions, including a presummit Conference organized by IFLA and the Biblioteca Alexandrina just before the Tunis Summit in Alexandria, Egypt, on the theme "Libraries: the information society in action." Here IFLA showcased success

stories illustrating the role of libraries in the Information Society. At the end of the presummit IFLA launched its *Alexandria Manifesto on Libraries, the Information Society in Action*.^[7] Thanks to intensive and sustained advocacy work by IFLA and its allies the WSIS outcome documents contained some very favorable language concerning the role of libraries in the Information Society. Since 2005, IFLA has continued to follow up the WSIS advocacy work, by monitoring the Internet Governance Forum and participating in the WSIS action line facilitation and consultation meetings held annually in Geneva. In 2006 IFLA set up a working group, designated as the President-elect's Information Society Working Group (now the President's Information Society Working Group), to keep abreast of progress in respect of the action lines and other important issues (such as Internet governance) arising from WSIS, but not limited to it. The work of this Working Group is closely aligned to the presidential theme of IFLA's 2007–2009 President, Claudia Lux, "Libraries on the agenda!"

In its advocacy at international bodies such as UNESCO and WIPO, IFLA's internationally representative membership lends it a unique credibility when it states the concerns and interests of the library profession.

LANGUAGES

The IFLA has seven working languages: Arabic, Chinese, English, French, German, Russian, and Spanish. The federation's policy is to provide a simultaneous interpretation service in these languages for the major sessions at the annual general congress. For this purpose IFLA has built up a team of volunteer interpreters who are skilled in the language of librarianship and information work. At its congresses the language of the host country is sometimes also used, if it is not one of the official working languages. Congress papers are also translated into the working languages, subject to the resources being available. Other meetings and seminars may also require the use of some of the working languages for translation or interpretation. Many IFLA publications appear not only in the seven official languages, but also in other languages. For example, the IFLA/UNESCO public library guidelines are available on IFLA's Web site in 21 languages, and the IFLA/UNESCO school library guidelines in 17. For many of these translations IFLA gratefully relies on volunteer translators and, more recently, on the language centers referred to below.

HEADQUARTERS

The IFLA Headquarters is headed by a secretary general, appointed by the Governing Board, who is responsible for the strategic and operational direction and financial

management of the federation, within the policies established by the General Assembly and the Governing Board. The secretary general has the right to attend and participate, in a nonvoting capacity, in all meetings of the General Assembly, the Governing Board, and the Professional Committee. The IFLA Headquarters consists of a small team of full- and part-time staff, based at in the Hague. It is hosted by the Koninklijke Bibliotheek (the Royal Library of the Netherlands), which provides the office space and the infrastructure.

Regional Offices

IFLA has established three regional offices: for Africa, Asia and Oceania, and Latin America and the Caribbean. Their regions correspond to those of the regional sections. The regional office for Africa is hosted by the University of South Africa in Pretoria, South Africa, the office for Asia and Oceania is hosted by the National Library Board of Singapore, while the office for Latin America and the Caribbean is hosted by the Biblioteca Pública do Estado do Rio de Janeiro, in Rio de Janeiro, Brazil. A regional manager heads each office. They receive modest funding from IFLA's central funds, but they also receive substantial support from their host organizations. They work closely with the regional sections and with the core activities to promote the work of IFLA in their region and to ensure that the needs of their region are reflected in the federation's policies and priorities. The International Federation of Library Associations and Institutions also has three language centers, for French (for Africa), Russian, and Arabic. The IFLA Center for Arabic Speaking Libraries and Information Institutions is hosted by the Bibliotheca Alexandrina, in Alexandria, Egypt; the IFLA French Language Center for Africa is hosted by the Central Library of Cheikh Anta Diop University, in Dakar, Senegal; and the IFLA Russian Language Center is hosted by the Russian State Library, in Moscow, Russian Federation. The regional offices are concerned with communication and recruitment tasks.

IFLA on the Internet

IFLA has had a presence on the Internet since 1993. It consists of a Web site, formerly called IFLANET (<http://www.ifla.org>), and a set of electronic mailing lists. It was initiated within the UDT core program in 1993 and hosted by the National Library of Canada (now Library and Archives Canada). From 2001 to 2008 it was hosted by the Institut de l'Information Scientifique et Technique (INIST), in Nancy, France. It is now administered by the IFLA Headquarters. As an essential tool for all those active in the work of the federation, it includes general information about IFLA, including all the professional units, details of future congresses, the papers presented at the general congress, lists of members and corporate

partners, complete publications and electronic collections, and reports on technologies and issues facing contemporary libraries. Use of the IFLA Web site has been increasing rapidly. In 2007 it logged an average of almost 290,000 visits per month. During 2008 the IFLA Web site was redeveloped and thoroughly updated, to convert it from a repository of documents to a multipurpose communication tool. The new site is based on a modern open-source content management system (Drupal). It provides clear and efficient navigation, an attractive Web presence for each of IFLA's professional units, and a range of Web 2.0 functionality, including blogs, wikis, and forums, to enable IFLA members to communicate, interact, and work together in innovative and flexible ways. Its design takes into account the seven official languages as well as the requirements of visually handicapped and bandwidth-challenged users. Because of the new site's higher demands on resources and hosting possibilities, it will be housed at another Web hosting company.

In 2008 there were 61 electronic mailing lists, including IFLA-L, a general electronic forum; LIBJOBS, a mailing list for librarians and information professionals seeking employment; IFLAPARL, the mailing list of the Section on Library and Research Services for Parliaments; and UNIMARC-DIS, a forum for those using or interested in the UNIMARC cataloging formats.

PUBLICATIONS

The results of the research, projects, and other activities of the federation's professional units are reflected in its publications. *IFLA Journal*, which covers the latest developments on the international library and information scene, is published quarterly by Sage Publications. Each issue provides current information on the federation, together with articles selected to reflect the many aspects of the international library and information profession.

The reports to the General Assembly of the President and the Secretary General are published annually in *IFLA Journal*, while a formal annual report is published separately. The *IFLA Directory* appears biennially. It provides information about the composition of IFLA's main steering bodies such as the Governing Board and the standing committees of all IFLA sections as well as other organizational information, including the Statutes and Rules of Procedure. The membership directory no longer appears in the *IFLA Directory*. Instead, it is now accessible online on the IFLA Web site.

IFLA produces a major series of monographs, *IFLA publications*, published on its behalf by K. G. Saur Verlag of Munich, Germany. Six titles are usually published each year, and they are available for separate purchase or by subscription as an optional addition to the membership fee. Recent titles include:

- Newspapers collection management: printed and digital challenges.^[8]
- Information Literacy: International Perspectives.^[9]
- Library Management and Marketing in a Multicultural World.^[10]
- Networking for Digital Preservation—Current Practice in 15 National Libraries.^[11]

The *IFLA Reports Series* consists of reports on congresses, surveys, and other studies, which do not warrant monograph publication. They are available for individual purchase. Recent titles include: *Guidelines for Library Services for Young Adults*^[12] and *Guidelines for Libraries of Government Departments*.^[13] In addition to this series, Saur also publishes the *IFLA Series on Bibliographic Control*.

Conclusion

From its modest beginning in 1927 as a kind of club of library associations and directors of major libraries in Europe and North America, IFLA has developed into a worldwide network of library associations, libraries, and librarians, exchanging information, developing guidelines to good practice, and influencing the world’s decision-making bodies in the service of libraries and their users.

International Federation of Television Archives (FIAT/IFTA)

Steve Bryant

BFI National Archive, Herts, U.K.

Abstract

The International Federation of Television Archives (FIAT/IFTA) is an international association of archives holding television programs and production material. Formed in 1977, it was initially made up of the archives of major broadcasting organizations, but grew to encompass national archives, technology companies, academic institutions, and others. Its main aim is information exchange, which it achieves through annual conferences, regional and specialist seminars, publications and its Web site. It cooperates with other international associations in its field and with UNESCO and attempts to draw attention to the historic importance of the audiovisual heritage throughout the world and to the dangers to its continued preservation. The recent growth of digital technologies and outlets has revolutionized the possibilities for television archives and brought a host of new concerns to FIAT/IFTAs agenda.

INTRODUCTION

The International Federation of Television Archives (formally titled *Fédération Internationale des Archives de Télévision*—commonly abbreviated to FIAT/IFTA) is, in its own words, “an international professional association established to provide a means for cooperation amongst broadcast and national audiovisual archives and libraries concerned with the collection, preservation and exploitation of moving image, and recorded sound materials and associated documentation” (source: FIAT/IFTA Web site home page). The means for cooperation include an annual conference, regional seminars, publications, and an online forum. Full members are organizations holding archives of television programming, while other bodies with an interest in the field, including commercial, industrial, and academic interests, are affiliated.

FOUNDATION AND CONSTITUTION

The International Federation of Television Archives was founded in Rome in 1977 by the heads of the archives of four broadcasting or audiovisual organizations: INA (Institut National de l’Audiovisuel-France), RAI (Radiotelevisione Italiana), the BBC (British Broadcasting Corporation), and the first German public channel, ARD. Statutes governed by French law were drawn up and members sought from around the world, although the bulk of the membership was, at first, and has largely remained European. Part of the reason for the establishment of the new organization was the failure of these broadcasters, despite the extensive nature of their holdings, to be accepted as equal members of the only existing forum for moving image archives, the *Fédération Internationale des Archives de Film* (FIAP). This

was, and remains, an organization of national film archives and cinémathèques, dedicated to establishing and enforcing exacting preservation and usage standards, and the industrial and commercial nature of much of the work of television archives, even those run by state or semi-state broadcasters, did not meet their criteria.

Nonetheless, the establishment of an international professional body dealing with the concerns of the program archives of television companies was a need felt in many countries and its foundation in the late 1970s was timely and reflected a crucial development stage of these archives. As with the archives of cinema output, television archives were formally established only when the medium had developed to a stage where a need for repositories of its history was felt—unfortunately too late to avoid the loss of crucial material from its formative years. In television, much early broadcast material was transmitted live, so there was nothing to keep anyway, and this transitory feeling worked against the establishment of archives. The earliest material to be collected was that which had been shot specially on film, particularly news and magazine program material, and, although the technology existed to record live output on film (telerecording or kinescope) from the late 1940s onwards, it was expensive and sparingly used, especially as copyright restrictions meant that anything other than the strictly factual was unlikely to be needed for rebroadcast—the main reason for keeping it in a broadcaster’s archive. When videotape was introduced in the late 1950s it revolutionized production but not archiving. It was expensive and, crucially, reusable. Most archive departments, which were actually really film libraries, did not even get control of it until the mid-1970s, as it required intricate machinery to replay, and thus remained the responsibility of engineering departments, whose priority was the next production rather than the last one.

At least, this was the case in Europe, where FIAT/IFTA was formed, and where most state broadcasting institutions followed the lead of the oldest and most prestigious broadcaster, the BBC. In the United States, the home of the largest TV production sector, the situation was different. Much more material survived because of the needs of syndication and different time-zones, and because much of the production in entertainment and drama was on film, through established Hollywood production companies. It is significant that the earliest and longest established American members of FIAT/IFTA were the New York-based news divisions of the three main networks, CBS, NBC, and ABC, whose concerns were the nearest to those of the European broadcasters.

In its first decade, then, FIAT/IFTA was composed mainly of state broadcasters from European countries. In most cases, these were the only broadcasters in those countries, as commercial competition was not a full reality everywhere until the 1990s, even in many areas that were not part of the Communist bloc, such as the Scandinavian countries. The United States was represented by the network news companies and, apart from Japan, Korea, Canada, Australasia and a handful of intrepid South Americans (most notably, Brazil), there was little representation from the rest of the World. In many places, especially Africa and parts of Asia, television itself was barely established, let alone its archives.

The constitution of the organization set up an Executive Council of 12 to run the organization, plus a President, all to be elected by the General Assembly, which is held every 2 years. The Federation also has a General Secretary and a Treasurer, chosen from the ranks of the Executive Council. All these officers must be employees of Full Member organizations (there are also associate and individual member categories) and give their time for free, though the organization can, and has, employed individuals for specific tasks. The main funding comes from members' subscriptions, though industry sponsorship has played an increasing role since the early 1990s. All the presidents to date have been heads of major European broadcasting or national archives, and the post has been held by the BBC, RAI, NRK (Norway), ORF (Austria), INA, and the Netherlands Institute for Sound and Vision.

CONFERENCES

From the very beginning, the Federation's main focus has been its annual conference, held in a different country each year. The financing of these events has traditionally fallen to a combination of the host member organization or organizations and the Federation itself, though sponsorship from television technology manufacturers, most notably Sony, and income from exhibition stands has become increasingly important. Though there is no hard and fast rule, a tradition has been established that one conference

in every four should be held outside Europe. Paris and Lisbon have been the venue for three conferences each, as has Italy, where RAI has always hosted, but in different cities, while London and Madrid have each held two conferences to date and the emerging television nations in Eastern Europe have also been prominent, with conferences held in Sofia (Bulgaria), Bogensee (near Berlin), and Budapest in the 1990s. Venues outside Europe have included Rio de Janeiro, Montreal, Tokyo, Washington, D.C., Santiago de Chile, New York and Beijing.

The annual conference is an opportunity for members to discuss mutual questions of interest, in formally structured plenary sessions with published papers, in workshop groups and, of course, in social gatherings. In the earliest years, the conference programs tended to be built around standing areas of concern, though later they came to be themed. It is fair to say that, in the first decade of FIAT/IFTA's existence, the main focus was on the members getting to know how others tackled similar problems to their own, whereas later the main focus became external pressures, particularly technological change and commercial opportunities. The main responsibility for the conference program falls to the Federation's commissions, established by the Executive Council to conduct research into specific areas of interest and to prepare the conference program. Like the Executive Council, the commissions are made up of volunteers with relevant experience from the membership, and chaired by a representative from the Council.

THE FIRST COMMISSIONS AND THEIR CONCERNS

The first three commissions to be established were the Documentation Commission, dealing mainly with issues of how to catalog moving image material; the Technical Commission, concerned with issues of broadcasting technology as they affected archives; and the Training Commission. Their reports made up a considerable volume of the early annual conferences and their documents, including the Documentation Commission's Minimum Data List (a standardized guide to what information must be documented about holdings—rather in the vein of later metadata standards like the Dublin Core) and the Glossary (a guide to useful television archive and technology terms in different languages) were regularly updated and distributed. One of the earliest technical issues to face FIAT/IFTA was the obsolescence of video formats, though this was a problem which emerged slowly.

The earliest focus for the Technical Commission was film preservation, but this was an issue already well covered by FIAF and the emphasis soon shifted to the greater problems posed by video. At the end of the 1970s, as FIAT/IFTA was being formed, the first broadcast video format, 2" Quadrex, was being replaced by the 1"

broadcast standard and portable camera formats, such as U-matic. Toward the end of the 1980s, manufacturers ceased to support the older technology, while large numbers of newer formats were about to be introduced, and it became clear that the central issue for television archives was how to ensure the preservation of material held on obsolete formats. This problem encompassed issues of standards for transfer, choice of new formats, maintenance of obsolete machinery and skill bases, making financial cases for transfer programs, selection on grounds of commercial value and cultural significance, and the particularly acute problems faced in developing countries—issues which stretched beyond the remit of the Technical Commission. Representatives of companies from the electronics manufacturing industry made up a panel at a FIAT/IFTA conference for the first time in Turin in 1991 and faced a hostile reception on this issue. It was, however, clear that their commercial imperatives demanded the regular introduction of newer formats and the phasing out of the old, and that what was needed was an ongoing dialog between the archives and the manufacturers, for which FIAT/IFTA has provided the main forum ever since.

MEMBERSHIP

In the early 1990s, membership of FIAT/IFTA spread more widely with the establishment of new commercial broadcasters in many countries and the growth of television around the world. The newer members were able to set up with the most recent (and increasingly cheaper) broadcast technologies and didn't (yet) face the problem of legacy collections on obsolete formats. Many of them didn't even know what a piece of film looked like. They had plenty to learn from other members about the establishment of archives, but their experiences of setting up from scratch also brought a fresh perspective to the organization.

Another area of membership growth was cultural organizations with responsibility for the preservation of television material. These followed either the model of the few national audiovisual archives with television operations, such as the British Film Institute or the Library of Congress, or that of the national organization with responsibility for the archives of the state broadcaster, such as INA. Some of them assumed preservation responsibilities, while others, like the Hungarian National Audiovisual Archives, offered a public access service. In the Netherlands, the creation of the Netherlands Institute for Sound and Vision (Beeldengeluid) from the merger of the archive of state broadcaster NOB and several government organizations, saw a new FIAT/IFTA member formed from several old ones. Some of these organizations were seen as a response to the economic problems of format obsolescence and the growing demand for public and academic access to historic material. Their growing significance in

FIAT/IFTA was reflected by the passing of the Presidency, traditionally held by a broadcasting organization, first to INA and then to Beeldengeluid.

INTERNATIONAL COOPERATION

The International Federation of Television Archives has been involved in international cooperation with other associations of audiovisual archives through the UNESCO Round Table of Audiovisual Archives, later renamed the Coordinating Council of Audiovisual Archive Associations, whose other members were initially FIAF, the International Association of Sound Archives (IASA) and the audiovisual sections of the International Council on Archives (ICA), and the International Federation of Library Associations. These have more recently been joined by the Association of Moving Image Archives and the Association of Recorded Sound Collections (ARSC), both mainly North American organizations, and the South East Asia-Pacific Audiovisual Archives Association. As well as information exchange and the coordination of training activities, the main practical outcome of this cooperation has been an irregular series of events under the banner of the Joint Technical Symposium, which have considered matters of audiovisual technology of common interest and which have been held in Paris, London, and Toronto. The International Federation of Television Archives also held some experimental joint conferences with IASA (Berlin, 1994) and IASA and ARSC (Washington, D.C., 1995).

Another outcome of this international cooperation has been some regional seminars which have been held in parts of the world where specific basic help has been required, particularly Africa, Latin America, South Asia, and Eastern Europe in the early 1990s. These have often been arranged in cooperation with the other associations, IASA being the most regular partner, and the venues have included Tunis, South Africa, the Caribbean, and Egypt. The International Federation of Television Archives has also aimed as far as possible to help archivists from distant or disadvantaged countries to attend its conferences, often using specially sought sponsorship, the most successful partnership being with the Organisation Internationale de la Francophonie, a French organization which has paid for delegates from French-speaking countries in Africa and elsewhere to attend conferences in Europe.

CHANGING EMPHASES

Changes in television structures and archive practices have been reflected over the years in changes to the FIAT/IFTA commission structure. In 1993, the first new Commission since the founding of the Federation was launched. This was the Programming and Production Commission, which was established to investigate issues

concerning the reuse of archival content and programs in the broadcast environment and public cultural spheres and to organize conference events considering program content. It was founded in the context of the expansion of the use of archive programming through repeat channels, public screenings, video releases, and an increasing number of programs about television history or using television archive material in a historical context. The commission produced two important documents: Selection Guidelines (for preservation purposes) and a video on misuses of archival material. The commission also organized the FIAT Award for the best use of archive material in a new program. The first award was given in 1994 (to Danmarks Radio) and thereafter became an annual highlight of the conference. Programs were nominated by members and screened at the conference, with members voting for the winner. This enabled delegates to consider different ways of reusing archival content in new programs and conference sessions and workshops were arranged featuring the producers of shortlisted programs.

Another growing aspect of the work of television archives considered by this commission was the sale of footage between broadcast companies. Strategies for publicizing these services ranged from presence at conferences to placing catalogs online, and FIAT/IFTA provided platforms for both furthering these developments and discussing the best strategies for success, often in collaboration with another international partner, the Federation of Commercial Audio-visual Libraries (FOCAL International).

Then, in the late 1990s, the Documentation Commission and the Technical Commission were merged, prompted by the convergence of recording and documentation technologies in the growing digital environment. From this merger came the Media Management Commission, considering all questions concerning of growing digitization and its effect on archives. The feeling grew that, with television production becoming tapeless, the broadcast company archivist needed to be involved with the documentation and preservation of material before transmission rather than after, or risk being cut out altogether. Rapidly digitizing companies such as Swedish Television (SVT) were at the forefront of this development and metadata issues were the key focus. A metadata guide by prominent FIAT/IFTA member, Annemieke de Jong of Beeldengeluid, became a key text and was translated into several languages with financial assistance from the Federation. However, many felt that traditional preservation issues were being overlooked because of the commission's emphasis on new technologies and, in 2007, a Preservation and Migration Commission was established to take over the role of the old Technical Commission and to reestablish the question of format problems on the FIAT/IFTA agenda. This problem had become particularly acute in developing countries, which lacked the resources for large-scale transfer programs, but was also still very much a live issue for even the most advanced organizations, as

there were still question marks over the viability of certain formats and over the best future strategies.

DIGITAL DEVELOPMENTS

By this time, FIAT/IFTA had itself entered the digital age, with its Web site (<http://www.fiatifta.org>) containing the papers from all its conferences and regional seminars, as well as all other key documents, a list of members and a forum for the online discussion of television archive questions or for those seeking advice. This, however, relies, as FIAT/IFTA always has, on hosting by the key member organizations linked to the Presidency or General Secretaryship.

The Federation had also itself been at the forefront of developing digital technologies. One of the best examples of the sort of cooperation between members which could be fostered by providing a platform for meetings was the Euromedia project, a successful bid by several FIAT/IFTA members, including Sudwestrundfunk of Germany, ORF, SVT, and the BBC, plus some German and Austrian technology providers, for European Union funds to develop a prototype digital asset management system. The progress of the system was regularly demonstrated at FIAT/IFTA conferences in the late 1990s and one of the technology companies, Tecmath of Germany, became a sponsor of the FIAT/IFTA Award. Other EU-funded projects with FIAT input followed, including the BIRTH project, a Web site featuring clips of early television productions, and Presto Space, a film and video preservation project.

THE CULTURAL AND ACADEMIC APPROACH

Television and its history is now the subject of academic study in many schools and universities and this too has been reflected in the developing FIAT/IFTA commission structure. The Television Studies Commission was established in 1999 to consider aspects of the academic study of television, using archives, and in particular to address the question of access to archive holdings. This had previously been the domain of the national archives and bodies such as INA, which have a long tradition of making their holdings available for study and to as wide a public as possible, whereas broadcasters had maintained their archives for their own uses and, in many cases, resisted demands to make them available for study, while others were accessible only to those with good contacts within the company. The main argument against allowing academic access had been the expense of copying materials, but cheap digital technologies have opened up wider possibilities, and many major broadcasters now include making material publicly and academically available as part of their digitization programs. The Television Studies Commission has also sought to introduce the results of academic work to the FIAT/IFTA membership, mainly

through conference sessions, and the increasing academic awareness of the value of television archives was reflected by the fact that the 2006 conference in Madrid, Spain, was hosted by a university rather than a broadcaster.

Public access to television archive material for cultural purposes is now a major aspect of the work of television archives. DVD releases of popular titles can be a lucrative commercial prospect, public or academic viewing of archival material through digital technology is available at such venues as the Bibliothèque Nationale in Paris or the BFI's Mediatheque in London, and many broadcasters now have plans to make their archives available online, both commercially and as a public service. Television history is now of interest to both the public and the academic community, for both nostalgic and sociological reasons, and its practitioners require access to the archives in order to tell it.

CONCLUSION

Television archives have had to adapt to changing television production techniques and changing recording technologies throughout their relatively brief period of existence. Now that the medium is mature enough to have its own history, to be regarded as a cultural phenomenon and thus be the object of academic study, and to have ever increasing outlets and demands for its past product, the archives have never had greater opportunities. Digital technologies have increased the possibilities for exploitation, but bring with them familiar problems in terms of ensuring long-term preservation and dealing with format obsolescence, on a greater scale than before. The requirement for an international forum, provided by FIAT/IFTA, will continue to be felt and to grow.

International Organization for Standardization (ISO)

Alan Bryden

International Organization for Standardization, Geneva, Switzerland

Catherine Dhérent

National Library of France, Paris, France

Abstract

ISO (International Organization for Standardization, <http://www.iso.org>) is the leading organization for the production and dissemination of consensus-based and globally relevant standards which provide a growing support to companies for becoming and remaining competitive in world markets. It is the world's largest developer and publisher of International Standards. The organization is a network of the national standards institutes of 157 countries, one member per country, with a Central Secretariat in Geneva, Switzerland, that coordinates the system. As a nongovernmental organization it forms a bridge between the public and private sectors. On the one hand, many of its member institutes are part of the governmental structure of their countries, or are mandated by their government. On the other hand, other members have their roots uniquely in the private sector, having been set up by national partnerships of industry associations. Therefore, ISO enables a consensus to be reached on solutions that meet both the requirements of business and the broader needs of society. This entry comprises three main sections: a general introduction to ISO and standards; an overview of ISO technical committee ISO/TC 46, Information and documentation, and an article by the Chair of ISO/TC 46 on "Managing information in a changing age."

DISCOVERING ISO

ISO (International Organization for Standardization, <http://www.iso.org>) is the leading organization for the production and dissemination of consensus-based and globally relevant standards which, in the context of globalization of trade and many other issues, such as the environment, security and health, provide a growing support to companies for becoming and remaining competitive in world markets. ISO is the world's largest developer and publisher of International Standards.

The organization is a network of the national standards institutes of 157 countries, one member per country, with a Central Secretariat in Geneva, Switzerland, that coordinates the system.

ISO is a nongovernmental organization that forms a bridge between the public and private sectors. On the one hand, many of its member institutes are part of the governmental structure of their countries, or are mandated by their government. On the other hand, other members have their roots uniquely in the private sector, having been set up by national partnerships of industry associations. Therefore, ISO enables a consensus to be reached on solutions that meet both the requirements of business and the broader needs of society.

ISO'S NAME

Because "International Organization for Standardization" would have different acronyms in different languages ("ISO" in English, "OIN" in French for *Organisation internationale de normalisation*), its founders decided to give it also a short, all-purpose name. They chose "ISO", derived from the Greek *isos*, meaning "equal". Whatever the country, whatever the language, the short form of the organization's name is always ISO.

Why Standards Matter

Standards make an enormous and positive contribution to most aspects of our lives. Standards ensure desirable characteristics of products and services such as quality, environmental friendliness, safety, reliability, efficiency and interoperability—and at an economical cost.

When products and services meet our expectations, we tend to take this for granted and be unaware of the role of standards. However, when standards are absent, we soon notice. We soon care when products turn out to be of poor quality, do not fit, are incompatible with equipment that we already have, are unreliable or dangerous. When products, systems, machinery and devices work

well and safely, it is often because they meet standards. And the organization responsible for many thousands of the standards which benefit the world is ISO.

What Standards Do

ISO standards:

- Make the development, manufacturing, and supply of products and services more efficient, safer, and cleaner.
- Facilitate trade between countries and make it fairer.
- Provide governments with a technical base for health, safety and environmental legislation, and conformity assessment.
- Share technological advances and good management practice.
- Disseminate innovation and accelerate the time-to-market of products and services derived from such innovation.
- Safeguard consumers, and users in general, of products and services.
- Make life simpler by providing solutions to common problems.

Who Standards Benefit

ISO standards provide technological, economic, and societal benefits.

- For businesses, the widespread adoption of International Standards means that suppliers can develop and offer products and services meeting specifications that have wide international acceptance in their sectors. Therefore, businesses using International Standards can compete on many more markets around the world.
- For innovators of new technologies, International Standards on aspects like terminology, compatibility, and safety speed up the dissemination of the innovations and their development into manufacturable and marketable products.
- For customers, the worldwide compatibility of technology which is achieved when products and services are based on International Standards gives them a broad choice of offers. They also benefit from the effects of competition among suppliers.
- For governments, International Standards provide the technological and scientific bases underpinning health, safety, and environmental legislation.
- For trade officials, International Standards create “a level playing field” for all competitors on those markets. The existence of divergent national or regional standards can create technical barriers to trade. International Standards are the technical means by which political trade agreements can be put into practice.

- For developing countries, International Standards that represent an international consensus on the state of the art are an important source of technological know-how. By defining the characteristics that products and services will be expected to meet on export markets, International Standards give developing countries a basis for making the right decisions when investing their scarce resources and thus avoid squandering them.
- For consumers, conformity of products and services to International Standards provides assurance about their quality, safety and reliability.
- For everyone, International Standards contribute to the quality of life in general by ensuring that the transport, machinery and tools we use are safe.
- For the planet we inhabit, International Standards on air, water, and soil quality, on emissions of gases and radiation and environmental aspects of products can contribute to efforts to preserve the environment.

The ISO Brand

• *Democratic*

Every full member of ISO has the right to take part in the development of any standard which it judges to be important to its country's economy. No matter what the size or strength of that economy, each participating member in ISO has one vote. Each country is on an equal footing to influence the direction of ISO's work at the strategic level, as well as the technical content of its individual standards.

• *Voluntary*

ISO standards are voluntary. As a nongovernmental organization, ISO has no legal authority to enforce the implementation of its standards. ISO does not regulate or legislate. However, countries may decide to adopt ISO standards—mainly those concerned with health, safety, or the environment—as regulations or refer to them in legislation, for which they provide the technical basis. In addition, although ISO standards are voluntary, they may become a market requirement, as has happened in the case of ISO 9001 quality management systems, or of dimensions of freight containers and bank cards. ISO itself does not regulate or legislate.

• *Market-driven*

ISO only develops standards for which there is a market requirement. The work is mainly carried out by experts from the industrial, technical, and business sectors which have asked for the standards, and which subsequently put them to use.

• *Consensus*

ISO standards are based on international consensus among the experts in the field. Consensus, like technology, evolves and ISO takes account both of evolving technology and of evolving interests by requiring a

periodic review of its standards at least every 5 years to decide whether they should be maintained, updated or withdrawn. In this way, ISO standards retain their position as the state of the art.

- *Globally relevant*

ISO standards are technical agreements which provide the framework for compatible technology worldwide. They are designed to be globally relevant—useful everywhere in the world.

HOW TO RECOGNIZE AN ISO STANDARD

In paper form, an ISO standard is published in A4 format, which is itself one of the ISO standard paper sizes. It may be anywhere between a four-page document and one several hundred pages' long. ISO standards are also available as electronic downloads and many are available as part of a collection on CD or in handbook. An ISO standard carries the ISO logo and the designation, "International Standard".

THE SCOPE OF ISO'S WORK

ISO has more than 17,000 International Standards in its current portfolio. ISO's work program ranges from standards for traditional activities, such as agriculture and construction, through mechanical engineering, manufacturing and distribution, to transport, medical devices, information and communication technologies, and to standards for good management practice and for services.

EXAMPLES OF THE BENEFITS STANDARDS PROVIDE

Standardization of screw threads helps to keep chairs, children's bicycles, and aircraft together and solves the repair and maintenance problems caused by a lack of standardization that were once a major headache for manufacturers and product users.

Standards establishing an international consensus on terminology make technology transfer easier and safer. They are an important stage in the advancement of new technologies and dissemination of innovation.

Without the standardized dimensions of freight containers, international trade would be slower and more expensive.

Without the standardization of telephone and banking cards, life would be more complicated.

A lack of standardization may even affect the quality of life itself: for the disabled, for example, when they are barred access to consumer products, public transport and buildings because the dimensions of wheelchairs and entrances are not standardized.

Standardized symbols provide danger warnings and information across linguistic frontiers.

Consensus on grades of various materials gives a common reference for suppliers and clients in business dealings.

Agreement on a sufficient number of variations of a product to meet most current applications allows economies of scale with cost benefits for both producers and consumers. An example is the standardization of paper sizes.

Standardization of performance or safety requirements of diverse equipment makes sure that users' needs are met while allowing individual manufacturers the freedom to design their own solution on how to meet those needs.

Standardized computer protocols allow products from different vendors to "talk" to each other.

Standardized documents speed up the transit of goods, or identify sensitive or dangerous cargoes that may be handled by people speaking different languages.

Standardization of connections and interfaces of all types ensures the compatibility of equipment of diverse origins and the interoperability of different technologies.

Agreement on test methods allows meaningful comparisons of products, or plays an important part in controlling pollution—whether by noise, vibration, or emissions.

Safety standards for machinery protect people at work, at play, at sea. . . and at the dentist's.

Without the international agreement contained in ISO standards on metric quantities and units, shopping and trade would be haphazard, science would be unscientific and technological development would be handicapped.

WHAT'S DIFFERENT ABOUT ISO 9001 AND ISO 14001

The vast majority of ISO standards are highly specific to a particular product, material, or process. However, ISO 9001 (quality) and ISO 14001 (environment) are "generic management system standards." "Generic" means that the same standard can be applied to any organization, large or small, whatever its product or service, in any sector of activity, and whether it is a business enterprise, a public administration, or a government department. ISO 9001 contains a generic set of requirements for implementing a quality management system and ISO 14001 for an environmental management system.

Generic standards can be applied to any organization. In recent years, new ISO management system standards have been developed and are now being rolled out worldwide. They include: ISO 22000 (food safety), ISO 28000 (supply chain security), and ISO/IEC 27001 (information security).

WHY CONFORMITY ASSESSMENT IS IMPORTANT

“Conformity assessment” means checking that products, materials, services, systems, processes, or people measure up to the specifications of a relevant standard or specification. Today, many products require testing for conformity with specifications or compliance with safety, or other regulations before they can be put on many markets. ISO guides and standards for conformity assessment represent an international consensus on best practice. Their use contributes to the consistency of conformity assessment worldwide and so facilitates trade.

WHAT “INTERNATIONAL STANDARDIZATION” MEANS

When the large majority of products or services in a particular business or industry sector conform to International Standards, a state of industry-wide standardization exists. The economic stakeholders concerned agree on specifications and criteria to be applied consistently in the classification of materials, in the manufacture and supply of products, in testing and analysis, in terminology and in the provision of services. In this way, International Standards provide a reference framework, or a common technological language, between suppliers and their customers. This facilitates trade and the transfer of technology.

ISO’S ORIGINS

In 1946, delegates from 25 countries met in London and decided to create a new international organization, of which the object would be “to facilitate the international coordination and unification of industrial standards.” The new organization, ISO, officially began operations on February 23, 1947, in Geneva, Switzerland.

WHO CAN JOIN ISO

Membership of ISO is open to national standards institutes most representative of standardization in their country (one member in each country).

- Full members, known as member bodies, each have one vote, whatever the size or strength of the economy of the country concerned.
- Correspondent members pay reduced membership fees. They are entitled to participate in any policy or technical body as observers, with no voting rights.
- Subscriber members also pay reduced membership fees. They are institutes from countries with very small

economies that nevertheless wish to maintain contact with international standardization.

Although individuals or enterprises are not eligible for membership, both have a range of opportunities for taking part in ISO’s work:

- Individuals may be selected by national member institutes to serve as experts on national delegations participating in ISO technical committees
- Individuals and enterprises may provide their input during the process of developing a national consensus for presentation by the delegation. This may be done through national mirror committees to the corresponding ISO technical committee
- International organizations and associations, both nongovernmental and representing industry sectors, can apply for liaison status to a technical committee. They do not vote, but can participate in the debates and the development of consensus.

There is a range of opportunities for taking part in ISO’s work.

How the ISO System Is Managed

All strategic decisions are referred to the ISO members, who meet for an annual General Assembly. The proposals put to the members are developed by the ISO Council, drawn from the membership as a whole, which resembles the board of directors of a business organization.

ISO Council meets twice a year and its membership is rotated to ensure that it is representative of ISO’s membership.

ISO’s operations are managed by a Secretary-General, which is a permanent appointment resembling the chief executive of a business enterprise. The Secretary-General reports to the ISO Council, the latter being chaired by the President who is a prominent figure in standardization or in business, elected for 2 years.

The Secretary-General is based at ISO Central Secretariat in Geneva, Switzerland, with a compact staff which provides administrative and technical support to the ISO members, coordinates the decentralized standards’ development program, and publishes the output.

How the ISO System Is Financed

ISO’s national members pay subscriptions that meet the operational cost of ISO’s Central Secretariat. The subscription paid by each member is in proportion to the country’s Gross National Income and trade figures. Another source of revenue is the sale of standards.

However, the operations of ISO Central Secretariat represent only about one-fifth of the cost of the system’s

operation. The main costs are borne by the member bodies that manage the specific standards development projects and the business organizations that provide experts to participate in the technical work. These organizations are, in effect, subsidizing the technical work by paying the travel costs of the experts and allowing them time to work on their ISO assignments.

HOW ISO DECIDES TO DEVELOP A STANDARD

ISO launches the development of new standards in response to sectors and stakeholders that express a clearly established need for them.

An industry sector or other stakeholder group typically communicates its requirement for a standard to one of ISO's national members. The latter then proposes the new work item to the relevant ISO technical committee developing standards in that area. New work items may also be proposed by organizations in liaison (see below) with such committees. When work items do not relate to existing committees, proposals may also be made by ISO members to set up new technical committees to cover new fields of activity.

To be accepted for development, a proposed work item must receive the majority support of the participating members of the ISO technical committee which, amongst other criteria, verifies the "global relevance" of the proposed item—this means that it indeed responds to an international need and will eventually be suitable for implementation on as broad a basis as possible worldwide.

WHO DEVELOPS ISO STANDARDS?

ISO standards are developed by technical committees, (subcommittees or project committees) comprising experts from the industrial, technical, and business sectors which have asked for the standards, and which subsequently put them to use. These experts may be joined by representatives of government agencies, testing laboratories, consumer associations, nongovernmental organizations, and academic circles.

Proposals to establish new technical committees are submitted to all ISO national member bodies, who may opt to be participating (P), observer (O) or nonmembers of the committee. The secretariat (i.e., the body providing the administrative support to the work of the committee) is allocated by the Technical Management Board (which itself reports to the ISO Council), usually to the ISO member body which made the proposal. The secretariat is responsible for nominating an individual to act as chair of the technical committee. The chair is formally appointed by the Technical Management Board.

Experts participate as national delegations, chosen by the ISO national member body for the country concerned.

National delegations are required to represent not just the views of the organizations in which their participating experts work, but those of other stakeholders too. National delegations are usually based on and supported by national mirror committees to which the delegations report.

According to ISO rules, the national member body is expected to take account of the views of all parties interested in the standard under development. This enables them to present a consolidated, national consensus position to the technical committee.

International and regional organizations from both business and the public sector may apply for liaison status to participate in developing a standard, or to be informed about the work. Such "organizations in liaisons" are accepted through voting by the relevant ISO committee. They may comment on successive drafts, propose new work items or even propose documents for "fast tracking," but they have no voting rights.

At the end of 2007, there were 3093 technical bodies in the ISO system, including 201 ISO technical committees. The focus of the technical committees is specialized and specific. In addition, ISO has three general policy development committees that provide strategic guidance for the standards' development work on cross-sector aspects. These committees ensure that the specific technical work is aligned with broader market and stakeholder group interests. They are:

- CASCO (conformity assessment)
- COPOLCO (consumer policy)
- DEVCO (developing country matters)

These may recommend the development of new standards for their stakeholder groups, which are then submitted to the approval process described above, or in the case of CASCO, develop new standards itself.

HOW ISO STANDARDS ARE DEVELOPED

The national delegations of experts of a committee meet to discuss, debate and argue until they reach consensus on a draft agreement. The "organizations in liaison" also take part in this work. In some cases, advanced work within these organizations means that substantial technical development and debate has already occurred, leading to some international recognition and in this case, a document may be submitted for "fast-track" processing. In both cases, the resulting document is circulated as a Draft International Standard (DIS) to all ISO's member bodies for voting and comment.

If the voting is in favor, the document, with eventual modifications, is circulated to the ISO members as a Final Draft International Standard (FDIS). If that vote is positive, the document is then published as an International Standard.

Every working day of the year, an average of seven ISO technical meetings takes place around the world. In between meetings, the experts continue the standards' development work by correspondence. Increasingly, their work is carried out by electronic means, which speeds up the development of standards and cuts travel costs.

- *Public access*

Most ISO members have some form of public review procedures for making proposed work items and draft standards known and available to interested parties. The ISO members then take account of any feedback they receive in formulating their position on the proposed work item or on the draft standard.

Draft standards are also available for sale to interested members of the public who can provide input through the ISO member in their country. The public can purchase International Standards through the ISO or through ISO's national members.

- *Consensus*

Because ISO standards are voluntary agreements, they need to be based on a solid consensus of international expert opinion. Consensus, which requires the resolution of substantial objections, is an essential procedural principle. Although it is necessary for the technical work to progress speedily, sufficient time is required before the approval stage for the discussion, negotiation and resolution of significant technical disagreements.

"Consensus" is officially defined (in ISO/IEC Guide 2) as "general agreement, characterized by the absence of sustained opposition to substantial issues by any important part of the concerned interests and by a process that involves seeking to take into account the views of all parties concerned and to reconcile any conflicting arguments." The definition notes, "Consensus need not imply unanimity."

- *Voting*

For a document to be accepted as an ISO International Standard, it must be approved by at least two-thirds of the ISO national members that participated in its development and not be disapproved by more than a quarter of all ISO members who vote on it.

- *Appeals*

ISO national member bodies have the right of appeal to a parent technical committee on the decision of subcommittee, to the Technical Management Board on a decision of technical committee and to the ISO Council on a decision of the Technical Management Board. Appeals may relate to procedural, technical, or administrative matters.

- *Review of International Standards*

All International Standards are reviewed at the least 3 years after publication and every 5 years after the first review by all the ISO member bodies. A majority of the P-members of the TC/SC decides whether an International Standard should be confirmed, revised or withdrawn.

ISO DELIVERABLES

In addition to International Standards, ISO can also offer other forms of normative agreements for situations where speedy publication is important, has developed a schematic representation of the different types of deliverable available. These include:

- ISO/PAS Publicly Available Specification
- ISO/TS Technical Specification
- ISO/TR Technical Report
- IWA International Workshop Agreement

ISO'S INTERNATIONAL PARTNERS

ISO collaborates with its partners in international standardization, the International Electrotechnical Commission (IEC) and International Telecommunication Union (ITU). The three organizations, all based in Geneva, Switzerland, have formed the World Standards Cooperation (WSC) to act as a strategic focus for collaboration and the promotion of international standardization.

ISO has a close relationship with the World Trade Organization (WTO) which particularly appreciates the contribution of ISO's standards to reducing technical barriers to trade.

ISO collaborates with the United Nations (UN) Organization and its specialized agencies and commissions, particularly those involved in the harmonization of regulations and public policies, such as:

- CODEX Alimentarius, on food safety measurement, management, and traceability.
- UN Economic Commission for Europe (UN/ECE), on the safety of motor vehicles and the transportation of dangerous goods.
- World Health Organization (WHO), on health technologies.
- International Maritime Organization (IMO), on transport security.
- World Tourism Organization (WTO-T), on the quality of services related to tourism.

In addition, ISO cooperates with UN organizations that provide assistance and support to developing countries, such as the United Nations Conference on Trade and Development (UNCTAD), the United Nations Industrial Development Organization (UNIDO), and the International Trade Centre (ITC).

ISO's technical committees have formal liaison relations with some 580 international and regional organizations.

ISO has reinforced its links too with international organizations representing different groups of stakeholders, including:

- World Economic Forum (WEF)
- Consumers International (CI)
- World Business Council for Sustainable Development (WBCSD)
- International Federation of Standards Users (IFAN)

Lastly, ISO also collaborates regularly with the major international organizations for metrology, quality and conformity assessment.

ISO'S REGIONAL PARTNERS

Many of ISO's members also belong to regional standardization organizations. ISO has recognized regional standards organizations representing Africa, the Arab countries, the area covered by the Commonwealth of Independent States, Europe, Latin America, the Pacific area, and the South-East Asia nations. The regional bodies commit themselves to adopt ISO standards as the national standards of their members.

ISO TECHNICAL COMMITTEE ISO/TC 46, INFORMATION AND DOCUMENTATION

Improving the production, classification and organization of documents and data is essential to avoid wasting human and financial resources.

—Catherine Dhérent
Chair, ISO/TC 46 (2006–2008)

Within ISO, technical committee ISO/ISO/TC 46, *Information and documentation*, has the responsibility for standardization of practices relating to libraries, documentation and information centers, publishing, archives, records management, museum documentation, indexing and abstracting services, and information science.

The Secretariat of the committee is held by AFNOR, the ISO member for France, and the national standards bodies of 34 countries participate in its work: Armenia (SARM), Australia (SA), Austria (ON), Bulgaria (BDS), Canada (SCC), China (SAC), Czech Republic (CNI), Denmark (DS), Egypt (EOS), Finland (SFS), Germany (DIN), Iran, Islamic Republic of (ISIRI), Ireland (NSAI), Italy (UNI), Japan (JISC), Kenya (KEBS), Korea, Republic of (KATS), the Netherlands (NEN), New Zealand (SNZ), Norway (SN), Poland (PKN), Portugal (IPQ), Russian Federation (GOST R), South Africa (SABS), Spain (AENOR), Sri Lanka (SLSI), Sweden (SIS), Switzerland (SNV), Thailand (TISI), the former Yugoslav Republic of Macedonia (ISRM), United States (ANSI), Ukraine (DSSU), and the United Kingdom (BSI). Another 39 countries have observer status.

In addition, the following organizations have liaison status with ISO/TC 46:

- International Documentation Committee, International Council of Museums (CIDOC)
- International Confederation of Societies of Authors and Composers (CISAC)
- International Digital Object Identifier System Foundation (DOI)
- European Association of Science Editors (EASE)
- European Commission (EC)
- International Atomic Energy Agency (IAEA)
- International Council on Archives (ICA)
- International Council for Scientific and Technical Information (ICSTI)
- International Federation of Library Associations and Institutions (IFLA)
- International Federation of Science Editors (IFSE)
- ISSN International Centre
- International Telecommunication Union (ITU)
- International Network for Terminology (TERMNET)
- United Nations (UN)
- United Nations Conference on Trade and Development (UNCTAD)
- United Nations Economic Commission for Europe (UN/ECE)
- Universal Postal Union (UPU)
- World Intellectual Property Organization (WIPO)

Established in 1947—the year that ISO began operating—ISO/ISO/TC 46 has 94 ISO International Standards in its current portfolio and 23 documents under development.

The following titles and short descriptions of the committee's subcommittees (CS) and working groups (WG) conveys a more detailed idea of the scope of its standardization work:

- WG 2, *Coding of country names and related entities*
- WG 3, *Conversion of written languages*
- WG 4, *Terminology of information and documentation*
- WG 5, *Archive boxes*
- SC 4, *Technical interoperability*
Standardization of protocols, schemas, etc., and related models and metadata for processes used by information organizations and content providers, including libraries, archives, museums, publishers, and other content producers.
- SC 8, *Quality—Statistics and performance evaluation*
Standardization of practices relating to the collection of statistics and performance indicators for information organizations and content providers, e.g., libraries, archives, museums, and publishers.
- SC 9, *Identification and description*
Standardization of information identifiers, description and associated metadata and models for use in information organizations (including libraries, museums,

and archives) and the content industries (including publishing and other content producers and providers).

- SC 11, *Archives/records management*
Standardization of principles for the creation and management of documents, records, and archives as evidence of transactions and covering all media including digital multimedia and paper.

In addition, SC 11 participates in a joint working group on document management application issues related to PDF/A files with SC 2, *Application issues*, of ISO/TC 171, *Document management applications*, and ISO/TC 42, *Photography*.

Over the past few decades, numerous standard tools have been conceived in the professional area on an international scale for identifying, classifying, finding, and exchanging all types of documents. These standards have been conceived in a context where the stability of the form of the document in space and time was controlled and where the use of computerized systems was centralized and dedicated to one type of application.

The production of electronic documentation and the transformation of structured, paper based business practices into automated work processes can in many instances lead to a loss of control, accountability, and structure in the electronic business environment. Providing guidance to facilitate records and information management in this context is a significant area in which ISO/TC 46 can contribute in the framework of its market environment.

With the production of electronic documents and the possibilities of exchanging digitized multimedia information on telematic networks, the traditional reference points for document maintenance have been dimmed, obliging the profession to question certain practices. The exchange of information is becoming generalized and concerns all sectors of activity; it is no longer about producing individual standards for the single sector of libraries and documentation, but to integrate in a process of multisectorial standardization, or risk being marginalized.

Adoption of open and generic standards has become imperative under these circumstances. If there is little immediate general demand, the whole realm of organization and individuals involved in formation is concerned by the work of ISO/TC 46 (libraries, archives, museums, document centers, publishers, producers, rights managers...) and to this effect, the economic impacts are real.

In this context, the following objectives have priority in the work of ISO/TC 46:

- Optimize the interoperability of systems related to archives, libraries, and museums.
- Take into account in standardization all the stages constituting the life cycle of a document (production, encoding, identification, management, diffusion, preservation) to assure the compatibility and coherence of the standards among themselves.

- Promote records management as a means to establish control and accountability in business environment.

EMBLEMATIC ISO/ISO/TC 46 STANDARDS

As the means to present, to classify, to sort, to display, to contextualize, to manage, to preserve... and finally to use the information in all industrial and intellectual areas, ISO/ISO/TC 46 plays a very important political and economic role. This becomes obvious when considering the use of some standards developed within ISO/ISO/TC 46, such as:

- ISO 3166, *Codes for the representation of names of countries and their subdivisions*. This is an essential example: the standard is used for internationalization of information as well as legal and diplomatic questions, on the Internet, e-business, and in many other contexts.
- Other standards such as: ISO 639, *Codes for languages* (developed by a joint working group of ISO/TC 37 and ISO/ISO/TC 46/SC 4), or ISO 690, *Bibliographic references—content, form and structure*, are universally used. (This standard is developed in a joint working group of ISO/TC 37 and ISO/ISO/TC 46/SC 4).
- For identification numbering, especially for the management of the rights of authors, producers, publishers, and so on. Any book, audiovisual work, textual work, music, film video, or sound recording has to be identified. The relevant standards for international numbering, such as the International Standard Book Number (ISBN), are developed by ISO/TC 46.
- For records management, which is a discipline that needs to be practiced by every organization in the world. Without appropriately managed records and the information and accountabilities they bring, organizations would not survive. The standard that covers this essential management process was created in ISO/TC 46.

THE MARKET FOR ISO/TC 46'S STANDARDS

The market served by ISO/TC 46 is characterized by a high degree of interdependence. Market players include for-profit (such as commercial businesses, system vendors, and publishers) and nonprofit institutions (such as libraries, documentation centers, archives, and museums). Increasingly there is convergence between the for-profit and the non-for-profit players as organizations assume multiple roles—often both supplying services to another institution and also the end user or consumer. The market is also moving to encompass the broader business environment as organizations become increasingly aware of the need to control, manage and effectively utilize their records and other forms of information.

Information and documentation supports the following information supply chain:

1. Creators of information (e.g., individuals within business, authors, performers)
2. Producers, distributors, and managers of information (e.g., publishers, printers, film and recording producers, booksellers, bibliographic networks, records management professionals, and archivists)
3. Organizers and providers of information to end users (e.g., librarians, booksellers, record sellers, museums, records managers, and archivists)
4. Preservers of information (e.g., archives, libraries, and museums)

The organizations and institutional groups dependent on ISO/TC 46 standards have overlapping responsibilities in the supply chain, but taken together represent the creation, dissemination, management, preservation, and consumption of documented information in all media: print, audio, visual, digital, etc.

STRUCTURE OF THE MARKET: SUPPLIERS/ MANUFACTURERS

- *Creators of information*

Creators include all public and private organizations and especially public agencies, and also the authors, editors, writers, compilers, performers, musicians, and all others originating information content. Most often this constituency is represented through professional organizations, such as authors' collectives, rights organizations, professional societies, etc. It also includes both individuals within businesses and the business organizations themselves that are required to create and maintain records of their activities.

- *Producers, distributors, and managers of information*
Producers and distributors include publishers (primary and secondary), distributors and information aggregators, and information intermediaries of information. These businesses serve primarily the end user providers of information products, such as booksellers, record stores, and libraries. Included are publishers in the commercial trade book sector; publishers focusing on the scholarly and scientific markets; medical and reference publishers; corporate business information providers; and producers of sound recordings and videos for all markets.

The book publisher market alone is huge. Standards applied by suppliers and manufacturers are critical to the effective functioning of the consumer part of this market.

Managers of information include all business organizations that are required, often by law, to have adequate frameworks in place for the protection and management

of their information resources. It also includes archival institutions with responsibility for ensuring the management through time of archival resources.

STRUCTURE OF THE MARKET: CUSTOMERS

- *Organizers and end user providers*

Organizers and end user providers describe a step in the information supply chain in which produced information "packages" are conveyed primarily to end users or consumers. The activities include organizing and providing access that enables end users to find information, then supplying the information products that satisfy their needs. The principal institutional groups that are the suppliers of organization of and access to information are libraries, archives, museums, and product sellers (on or off-line, for all media).

The customers for this information are the end users. The organization and supply process requires standards to enable services across institutions, including standards for data elements, protocols, search types, data formats, object descriptions, object classification, language codes, country codes, specification of access and security rules, and other forms of metadata. The organizers and suppliers may also need standards to acquire information objects such as product numbers, acquisition metadata. To enable various technologies to be used in organizing and delivering information, specialized software is created that follows the above standards.

- *Archives and preservation*

There is a large market segment that has responsibility for archiving and preserving information for use by future generations. These range from preservation and conservation laboratories housed in most large libraries and archives, to records management departments associated with many organizations, to sound and film archives maintained by associations and other organizations, to formal government and nongovernment archives. These groups have special needs for making information sustainable, be it printed, electronic, sound, or image media, and are dependent on a variety of suppliers for critical components in the archiving process. Standards are essential for trying to carry out the work in a cost effective and consistent manner.

MAJOR FACTORS IMPACTING THE MARKET

Some of the main evolutions and market trends that will have an impact on the development of the information and documentation field are the following:

- Major technical evolution from creation, distribution, and storage of information in paper form to electronic

form, and transformation of business processes from controlled paper-based activities to uncontrolled electronic processes.

- Convergence of media into multimedia information objects, making the creation, manufacture, organization, dissemination, and storage of information objects more complex.
- Increase in distance-learning initiatives and computer-based training developments that require new standards and challenge the information distribution mechanisms used today.
- The increasing dependence on and intersection with Web standards that are developed outside the TC and even outside ISO.
- Need for best practice-type guidelines in place of formal standards where media are new and sound standards cannot yet be developed.
- Pressure for shorter time scales for development of standards with parallel pressure to s that they are globally accepted.
- Increasing dependence on outsourcing by various segments of the community, requiring standards to be in place to be able to outsource efficiently and confidently.
- Growing interest in ISO 9001 quality management and development of related standards tools to make it effective across the many facets of the information and documentation area.
- Increasing need for statistics methodologies and standards for use with this diverse and not easily quantified market, to be used to support budgets and growth.
- Multilingual research in a Web environment.
- Some aspects of knowledge management and information management in a shared environment.
- Definition of the best devices for preservation of the collections in archives, libraries and museums.

BENEFITS EXPECTED FROM THE WORK OF ISO/TC 46

The benefits of standards in the information community are enormous but not easy to quantify. They include especially:

- Interoperability of information systems and resource hosts
- Cost savings through increased competition
- Better delivery through more choice
- Increase of universal access to information
- Assurance of protection to rights holders
- Preservation of cultural heritage
- Better management of information
- Sound bases for development of enabling supporting systems

- More accountable business practices.

ISO/TC 46'S OBJECTIVES

Based on the above considerations and on the multidisciplinary and the multiapplicability of standards developed by ISO/TC 46, the committee has defined the following objectives:

Scope

- To ensure the creation of timely and appropriate standards governing all facets of information and documentation.
- To ensure interoperability and harmonization among systems concerned with information and documentation.
- To adapt standards in a proactive way to emerging media or techniques, based on continuing observation of emerging market needs.
- To facilitate and encourage the effective and accountable operation of systems and processes associated with information and documentation.

Quality

- To ensure consistency among standards that deal with different facets of information and documentation and consistency with the other ISO standards.
- To encourage comprehensive input from all types of bodies concerned with information and documentation, including libraries, publishers, archives, business organizations, public sector bodies, museums, vendors, systems vendors, W3C, etc.
- To improve the worldwide representation of experts on the committee.
- To finalize and publish standards in a timely fashion to ensure focus and coordinated efforts, and avoid obsolescence.

Adoption

- To encourage the private and public sectors in the use of existing ISO standards and show the value of using ISO standards.
- To be responsive to the needs of potential standards users to ensure that standards are optimized in terms of usability and relevance.

(More information on ISO/TC 46, including its membership, contact details, business plan, work program and list of published standards can be accessed on the ISO Web site <http://www.iso.org>. Click on "Standards development" and then on "List of technical committees.")

MANAGING INFORMATION IN A CHANGING AGE

(This text was first published in the April 2008 issue of *ISO Focus* magazine <http://www.iso.org/isofocus> which featured various aspects of ISO's standardization work for information and document management.)

Information and document management is a crucial part of the daily functioning of any organization. It plays an important role in ensuring their performance and security, as well as promoting efficient relationships between them. However, creating, finding and communicating the most relevant information to the audiences who really need it through the most appropriate and simple means, is no easy feat. Which results in many people complaining that information is too widely spread, not easy to find, identify or criticize.

Several ISO technical committees are working to respond to these challenges, by addressing issues from the identification to the preservation of the content and of metadata, by way of their production and organization. This is especially true of course, for the electronic formats of information. Here the available support is often more fragile than the worst and most acid of papers. We need strong best practices to preserve electronic data and documents in the middle and long terms.

A widely recognized basic ISO standard which addresses this issue is OAIS (Open Archive Initiative Standard). It was originally proposed by the aerospace industry, anxious to maintain permanent access, understanding and reusability of the huge amounts of data it produces (and requires), which can span decades or even centuries.

The purpose of this general model is to establish a system for archiving information (both digitized and physical), with an organizational scheme composed of people who accept the responsibility of preserving information and making it available to a designated community.

This model must now be completed by other users, which explains why Web archiving experts recently

launched a new standard project on the identification of data packets during their transfer to a virtual archive in the context of OAIS.

This identification is in fact crucial for exchanging data adequately, and for managing intellectual and economic rights. In fact, it is necessary to identify all elements of information in the greatest detail, so as to deal in the most appropriate manner with the rights of authors, producers, and publishers, while at the same time providing exactly what the public requires.

We are now able to identify even the smallest part of an author's work, which though it can be made available to all interested parties (on the Web for instance), still ensures a fair retribution and acknowledgement of its author. At the same time, there is also an ongoing attempt to identify authors, producers, publishers, and others, a more delicate task, as it involves the description of individuals rather than their work.

The improvement of the production, classification, and organization of the main documents and data is also essential to avoid wasting of human and financial resources. It is the aim of the records management standards to help institutions better produce the information needed to prove their rights and obligations towards their stakeholders.

It would be fruitful experience for ISO to first coordinate the management of its own documentation in relation with that of its national bodies. The great challenge is to identify what must be preserved, for what purpose and for how many years and where? We must not waste time nor money. It is crucial that we immediately provide the right information to the right person.

International Records Management Standards ISO 15489 and 23081

Barbara Reed

Recordkeeping Innovation, Sydney, New South Wales, Australia

Abstract

The first international standard on records management, ISO 15489, was issued in 2001, followed in 2006/2007 by standards on Metadata for Records, ISO 23081. This entry outlines the history of the development of these standards and provides an overview of their contents. The impact of the records management standards is discussed followed by an assessment of the strategic uses of such standardization work.

INTRODUCTION

The International Standard on Records Management ISO 15489: Information and Documentation, Records Management, was formally launched in Montreal in November 2001. It consists of two parts: Part 1: General and Part 2: Guidelines. The Standard has been endorsed for adoption for a further period of 5 years, and is now due for review in 2011. Following the publication of the Records Management Standard, the Committee charged with establishing and administering records management standards (ISO TC 46 SC11) has issued further standards, most notably ISO 23081 on Metadata for Records, and its accompanying Guidelines for Implementation. Other work on developing technical reports as ancillary documents to support the implementation of specific aspects of the standard is underway.

This entry discusses the ISO 15489, Records Management Standard in terms of its history, development, and contents. It then discusses the history, development, and content of ISO 23081, Metadata for Records. The entry concludes with an assessment of the impact of the standards and a consideration of the strategic uses of such standardization work.

Background to the Development of ISO 15489

Within the Australian recordkeeping community, the requirement for a standard on recordkeeping was identified in 1992 emerging from discussions on implementing quality systems in compliance with requirements in the ISO 9000 series of standards. What constituted good recordkeeping to support quality management? It is noteworthy that this question first arose from the private sector, rather than the government sector most commonly identified with formalized recordkeeping. Answering that question engaged the Australian recordkeeping

community in 5 years of collaborative work between 1992 and 1997, a period of intense creativity and rethinking in the Australian recordkeeping community, culminating in the publication of AS 4390-1996, the Australian Standard on Records Management.^[1] This Standard was issued in six parts, each covering a major functional area of recordkeeping.

In 1997, following a suggestion to the International Standards Organization to adopt the Australian standard as an international standard, a ballot was held internationally across the participating national standards organizations. The results were sufficient to adopt the Australian standard as an international standard in a fast track process, but because considerable interest in the document had been evidenced in the process of balloting and some divergent views raised, it was determined that a more appropriate outcome would be to form an international project to establish consensus in the content of a Records Management Standard.

Work commenced on internationalizing the Australian standard in 1998 using the existing Australian work as the base document for development. The existing six-part structure was merged into a single document for consideration. Considerable debate and discussion ensued in the next few years.

Some of the concepts and content of the Australian standard were thought to be specific to the national practice. Different methodologies for achieving specific recordkeeping outcomes were posited as equally valid. Initial attempts to create a set of appendices to the document outlining jurisdiction specific practices resulted in a document which was unmanageably large and cumbersome. The decision to separate the broad principles into Part 1: General and the more particular methodological approaches into Part 2: Guidelines overcame this impasse. As work progressed on Part 2, the more methodological approaches, consensus on approach was achieved as similarities were emphasized rather than differences.

EVOLUTION FROM THE BASE AUSTRALIAN STANDARD

Of particular note in the formative discussions was the need to gain consensus on the definition of record, which was strongly articulated in the Australian work as “evidence of business activity.” This articulation was the result of a number of years of extensive and introspective discussion in the Australian recordkeeping context, and was a view that was vigorously defended in the international sphere. The conceptual alignment of the Australian view to the European notions of a singular conception of record/archive created an interesting alignment of interests and something of a dichotomy in the international English-speaking records community, in which U.K.- and U.S.-based colleagues advocated a distinct difference between records and archives. The Australian view of recordkeeping, a very broad conceptual approach providing a framework consistent with the records continuum view, encompassed records in all contexts including their archival manifestations. This provided ground for much discussion. In the end, a compromise position on this was adopted which gave ground to the notion of a separate “records management” regime.

Other views were staunchly defended, including the strong emphasis on records being closely linked and aligned to the organizational functions and activities that resulted in their creation. The process of records classification was particularly controversial, but the close connection between functions and activities, the role of records and the importance of the central concept of provenance in interpreting records prevailed over alternative views which suggested that more library-oriented approaches to classification be adopted. Similarly controversial was the Australian concept of appraisal which expanded the traditional notion of appraisal from a process of evaluating the disposal and retention requirements for records into a broader notion encompassing defining what records were determined for creation/capture. This could not be reconciled. Appraisal therefore is not specifically mentioned as a process within the standard, but rather the two concepts—“determining documents to be captured into a records system” and “determining how long to retain records”—are independently addressed.

A tension in traditions of recordkeeping needed to be articulated and resolved. The traditional approach to records management in the United States supported primarily “post-action” controls. That is, records management controls were applied after the business action was completed. In contrast, the document being discussed for international adoption articulated a “pre-control” framework, where control of documents as records from the time they were received into an organizational framework, both prior to and during the conduct of the business action. This pre-action framework was more aligned to the European traditions of recordkeeping.

Work on the internationalization of the standard was taking place in the late 1990s in an environment where the management of electronic records as business enablers was really only beginning. Countries were at different stages in their attempts to control the proliferation of information in the workplace. Tensions were apparent between paper-based processes and the need to rethink those processes into an electronic world.

Much of the initial work in the development of the ISO 15489 came from establishing mutual understanding across language and cultural barriers and establishing a strong community respect for the views of diverse traditions and approaches to recordkeeping. The close alignment of records and archives in European countries with little distinction between the two created both an opportunity for knitting a closer conceptual bonding of records in all environments, but at the same time, a barrier to achieving the work in hand. It is possibly unfortunate in the longer term that the introduction of a new term “records management” into many non-English speaking countries seems to have undermined the conceptual unity in the European view. This conceptual unity was very present in the Australian notion of recordkeeping, but unable to be sustained at the time.

CONTENT OF THE STANDARD

ISO 15489 Part 1: General,^[2] following introductory matters (Sections 1–3) contains:

- Statements outlining the organizational benefits of records management (Section 4).
- Clear requirements to locate and contextualize records management within the organizational and regulatory environment (Section 5).
- Concise statements of the responsibilities for records, including strong statements that recordkeeping roles are implicit in the activities of all employees, overall responsibility for programs and resources reside with management layers within organizations, while specific responsibility for establishing systems, frameworks and implementation reside with recordkeeping professionals (Section 6).
- Characteristics of records programs, records and records systems are outlined, including high level statements on their requirement to ensure that records survive as long as they are needed, which may be beyond the boundaries of specific technological applications implemented to manage records (Section 7).
- A high level statement of a methodology to achieve records management within an organization (Section 8).
- Records management processes including creation, retention, registration, classification, storage and handling, access and security, tracking, location, and implementing disposition (Section 9).

- Monitoring and auditing requirements (Section 10) and
- Training requirements (Section 11).

Perhaps the section of the standard of greatest strategic reach is that defining the characteristics of records. Section 7.2, which owes a debt to the InterPARES 1 research project,^[3] clearly identifies the distinction between records and other types of information resources in terms of their defining characteristics of authenticity, integrity, reliability, and usability.

ISO 15489 Part 2: Guidelines,^[4] broadly follows the structure of Part 1 of the Standard, providing greater detail on the methodological approach known as “Developing and Implementing Records Systems” (Section 3). It echoes the structure of Section 9 of Part 1 of the Standard in expanding on the specific processes of recordkeeping (Section 4), and in expanding on requirements for monitoring and auditing (Section 5), and training (Section 6). Part 2 contains two annexes which map between the Guidelines and the general requirements in Part 1.

ISO 23081, Metadata for Records

The second suite of standards to emerge from the international standards committee on Records Management is ISO 23081: Information and documentation, Records Management Processes, Metadata for Records. This standard also exists in two parts: Part 1 being “Principles” (published in 2006)^[5] and Part 2 is “Conceptual and Implementation Issues” (published in 2007 as a technical specification but being proposed as an international standard).^[6]

Recordkeeping metadata is of key importance in managing records in the electronic world. Articulating the recordkeeping requirements for metadata positions the recordkeeping community to contribute strongly to an emerging technical dialogue defining the behavior and characteristics of electronic information. The goal of articulating recordkeeping metadata is to ensure that particular resources can act as authoritative evidence of business action in the electronic world. This involves records being sustainable over application system boundaries in ways that render them able to be used and interpreted for as long as they are required. The conceptual stance of the metadata standard is to provide a unifying framework for the management of metadata about records regardless of their location, or age, or custody. Thus, it addresses records in all domains of action, including current operational systems, but stretching to records in archival repositories. Recordkeeping metadata, while by no means restricted to electronic records, none the less has a greater immediate and strategic impact in the electronic world.

BACKGROUND TO THE DEVELOPMENT OF THE STANDARD

Recordkeeping metadata was first addressed in research projects, that of the University of Pittsburgh (U.S.) project “Functional Requirements for Evidence in Recordkeeping,” 1993–1996,^[7,8] and following that Monash University’s (Australia) project “Recordkeeping Metadata Standards for Managing and Accessing Information Resources in Networked Environments Over Time for Government, Commerce, Social, and Cultural Purposes,” 1998–1999.^[9] Using these projects as a basis, a number of recordkeeping metadata element sets were developed for specific jurisdictional purposes.^[10–12] This was an area that was suited to an international standardization process seeking uniformity across requirements to enable vendor uptake and incorporation into application systems for records. In Australia, as various local jurisdictions adopted variations from the metadata standards established, forming a cohesive specification was seen as particularly desirable. There will always be a need for local and tailored implementation specific variables in recordkeeping metadata. The Australian Standards development community created generic models and high level guidance in these areas at the same time as the international community was working on the principles for recordkeeping metadata. The two sets of work were merged, with the Australian work being incorporated into Part 2 of the international standard.

CONTENT OF THE METADATA STANDARD

At the level of an international standard, the nature of the guidance provided to the implementing community is different from that applicable within a specific jurisdiction or domain. Thus the International Standard on Metadata for Records defines a framework and principles within which specific jurisdictions can further define their implementation guidelines. It positions recordkeeping metadata in relation to metadata from other closely related information disciplines and purposes—for example, information resource discovery, e-commerce, preservation and rights management (Section 7).

Part 1 of the Metadata for Records standards outlines the principles involved in defining records metadata. It adopts the following model of recordkeeping (Fig. 1) to illustrate the concepts:

The standard then outlines the requirements for recordkeeping metadata to fulfill the requirements outlined in the ISO 15489, International Standard on Records Management (Section 9.2). While the standard restricts its scope to the business environment implicit in the domain of records management, the models and principles it outlines applies to records regardless of their age,

Fig. 1 Main metadata types and their relationships. This model provides a conceptual approach to managing records in their context. Records are conceptualized as existing within a web of relationships to people (agents, structures), business (functions and activities), and mandates (legislation, authorizing competencies, policies, delegations). This view enables metadata to be identified for each of these separate entities and linked together via relationships, rather than having to be encompassed within the notion of the record itself. In metadata terms, this allows many different implementation options to be explored and articulated as suits the capacity and technological capability of the implementation site.

Source: From ISO 23081-1,^[13] Derived from Figure 2: Recordkeeping and Figure 3: The Business Context, included in Mckemmish.^[14]

format, or location, thus acting as a unified recordkeeping model for metadata in all environments.

One of the most important concepts outlined in the standard is the distinction between:

- Metadata assigned at the point of capture of a record into a management system which defines its context of creation and its structural and technical properties at a specific point in time.
- Recordkeeping process metadata which continues to accumulate as business and recordkeeping actions take place on the record (Section 5.2).

This notion is a powerful means of communicating the characteristics of records required to be addressed in the electronic world. It also distinguishes recordkeeping metadata from some other types of metadata in emphasizing the continual accumulation of metadata and requirements for automatic capture of this metadata as opposed to manual methods of “cataloging” or attributing user specified metadata.

Part 2 of the International Standard on Metadata for Records focuses on the conceptual and implementation issues involved in implementing recordkeeping metadata, covering issues such as developing schemas (Section 10), organizational variables in implementation and requirements for managing recordkeeping for metadata itself (Section 11). It provides guidance on implementing recordkeeping metadata in a relational way managing multiple entities and their continuing relationships over time or alternatively by “flattening” the multiple entities into fewer or even a single entity (Section 6.3). The notion of aggregation and aggregation levels required to manage records is discussed with a standardized scheme established to identify equivalence of aggregations across different implementations and to assist in implementing

recordkeeping interoperability (Section 7.1). A generic recordkeeping metadata model (Fig. 2) for defining specific types of elements required to manage records is introduced and elaborated (Sections 8 and 9).

Impact of Records Management Standards

A formal study of the impact of the ISO 15489 has been undertaken studying its uptake and impact in the United Kingdom^[15,16] In that research, the organizational context, circumstances, and size of the organization were determined to be a key determinant in the uptake and influence of the Standard on organizational behavior.

Fig. 2 Generic metadata model for managing records.

Source: From Figure 6 in *ISO/TS 23081-2: Information and Documentation, Records Management Processes, Metadata for Records, Part 2: Conceptual and Implementation Issues*; International Standards Organisation: Geneva, Switzerland, 2007, Section 8.1.^[17]

However, other less precise measures exist to attest to the importance of records standard in the international context. The quantity of international sales of the ISO 15489 standard are reputed to rival the quantity of sales of the ISO 9000 suite.^[16]

Every year, more countries join the community of developers actively participating in the Committee meetings to determine the scope, direction, and development of the Standards. In November 2007, over 120 active participants were registered within the international standards committee, representing over 26 individual countries, with a further 12 countries registered as “observers” to the Committee.^[18] The Standard has been translated into over 10 languages, and representatives of each continent (with the exception of South America) are active participants. The Euro-Centric nature of ISO development and the English-speaking origins of the original ISO 15489 work has been superseded by a truly international community.

Role of Standards

Establishing standards is often a two-edged sword. On the one hand, codifying a body of practice to ensure it is carried out consistently vies with the other view that codifying practice means stifling innovation. The process nature of the ISO 15489 and the breadth of vision of the ISO 23081 standards attempt to mitigate against the evils of the latter. However, in aspiring to standards that enable rather than restrict, some frustration about lack of precision results.

Standards serve multiple purposes. In recordkeeping, our standards can be viewed from any one of the following perspectives:

- *As a place marker:* In this role, the standards setting work clearly articulates the concepts of recordkeeping, its importance and its specific characteristics. This acts as a clear delineator of recordkeeping from other methods of managing information. It stands in contrast to homogenizing views that everything is just information and that particular disciplines are merely guarding their professional domain in not accepting such a homogenized view. Similarly, it acts as a clear statement to others outside the recordkeeping profession who, for a variety of reasons, wish to restrict the scope of records practice to those areas applying only to paper-based records, to disposal and retention or to compliance issues.
- *As a set of facilitative tools:* The standards established in this domain have been adopted and adapted by a number of specific jurisdictions and by individual organizations seeking to achieve best practice. In adopting the frameworks and principles, the requirements for more and further definition and attention to specific aspects of recordkeeping have been identified,

creating an ongoing tide of development fuelling a process of continuing improvement.

- *As a means of profession building:* Providing international standards which set out clearly an area of specialized practice enables profession building. Once standards exist they can be cited by organizations and in other standards. They act as means of professionalizing the practice of recordkeeping. This is particularly important in the electronic environment where the homogenizing effect of generic information management has undermined the records’ specific tasks in systems design and organizational consciousness. The standards act as strong statements from which individual practitioners can launch their claims to attention within organizations, as well as provide guidance on how to achieve the required outcomes.
- *As a means of improving practice:* The recordkeeping standards have been defined to be slightly ahead of practice. They have an agenda-setting role rather than just documenting the status quo. This is an important role of standards, but must be done knowingly and with a clear strategic vision.
- *As a means of achieving a significant mass:* The fact that these recordkeeping standards are international standards creates a worldwide community advocating and requiring the same outcomes. Records practitioners are a small group relative to other professional groupings in information management. Achieving international consensus increases the power of an individual disciplinary requirement, enabling a much greater degree of influence to be exerted. This can be seen in the impact in the vendor community developing software to manage records. The consolidated international market is big enough to have an effect in product direction and outcomes required, where individual fragmented smaller groups may never achieve sufficient strategic leverage.

CONTINUING WORK

The work of the ISO TC 46/SC11 Committee charged with developing international standards in recordkeeping is continuing. A further standard published is ISO 23310-2006, Information and Documentation: Guidelines for Standards Drafters for Stating Records Management in Standards, a standard geared to ensuring the appropriate inclusion of recordkeeping requirements into other standards.

Work is progressing on developing standard or technical reports on Work Process Analysis for Recordkeeping, Digitization, defining long-term retention requirements of electronic records, digital records conversion and migration. A recent strategic decision to move the Records Standards family into a Management Systems Structure is designed to enhance the status, impact, and coherence of the records standards.

CONCLUSION

The development of international standards for record-keeping has created a community of practitioners that extends worldwide, bridging language barriers. The impact of the work is evident in the adoption of the Standard into multiple jurisdictions and an increased international coherence in practice. Work continues within the standards development community to produce the next generation of standards and guidance to support implementations.

International Records Management Trust

Anne Thurston

International Records Management Trust, London, U.K.

Abstract

The significance of reliable and trustworthy records for public sector accountability and effectiveness, and the impact on citizens' rights when they are not managed, is far greater than is often realized. Records are the clearest and most durable evidence of the organization's operations, decisions, and activities. They are the underpinning factor in good governance. The International Records Management Trust (IRMT), a UK-registered charity governed by a board of trustees, exists for the sole purpose of supporting lower-resource countries in tackling the issues involved in managing public sector records as an essential national resource.

The IRMT was created in 1989 in response to a global study that documented widespread and progressive deterioration in the management of public sector records. It has always emphasized the significance of well-managed records for protecting and supporting citizens' interests as the evidence base for national and international development. It works with governments around the world to strengthen records systems as a basis for improved services for citizens; effective resource management; open, accountable, and transparent democracies; and national historical identity. From the time of its establishment, the IRMT has been committed to working with records professionals and their governments to find and apply new solutions for managing official records. In an environment of rapid administrative and technological change, it has become ever more important to find new solutions to protecting records as evidence.

INTRODUCTION

International efforts to reduce poverty, control corruption, strengthen democracy, and increase openness all depend on an evidence base of authentic records. In the rapidly evolving digital information environment, there are growing expectations for using information to support openness and digital development. However, information benefits are not automatic. The digital information created and held in IT systems is highly vulnerable; its value as evidence can easily be diminished or lost. An information governance/records management framework is essential to protect the availability and integrity of this evidence and to ensure that it provides a reliable evidence base for meeting development goals. The International Records Management Trust (IRMT) works with governments to help build this framework.

The IRMT is unique in its attention to the close relationship between records and good governance. A UK-registered charity governed by a board of trustees, the IRMT, was created in 1989 in response to a global study involving visits to several dozen lower-resource countries across the world where it was observed that records systems were weak and in many cases had decayed into informality. In some countries, information had become so difficult to retrieve that government operations relied increasingly on memory. In the paper environment, the loss of control of information integrity and of access to information resulting from weak record keeping had

created an open door for corruption, misuse of resources, and abuse of citizens' rights.

Managing records efficiently will not, in itself, halt corruption, protect citizens' rights, and bring about good governance, but development goals cannot be achieved without trustworthy evidence. There are now great hopes that digital government will provide solutions, but the speed with which information technologies are being adopted around the world is not being matched by the skills and infrastructure needed to manage the records they generate, with the result that the accurate information needed to support economic growth, the rule of law, and initiatives aimed at supporting transparency and accountability are undermined.

Over the last two and a half decades, the IRMT has worked with governments around the world to strengthen paper and digital records systems as a basis for improved services for citizens, effective resource management, and increasingly accountable and transparent democracies. The IRMT's program of work is funded by grants and contracts from national and international development agencies that have included the World Bank, the UK Department for International Development, the Commonwealth Secretariat, the Canadian International Development Research Centre, and the United Nations Development Program.

The IRMT works continually to identify new ways of collaborating with governments, international agencies, and records professionals to articulate the requirements

for managing records as evidence and to apply international good practice to meet local requirements in support of evidence-based governance. The IRMT employs core staff in London, works with a large team of international consultants, and liaises with a range of professional associations, consultancy firms, academic institutions, and NGOs to define strategies and deliver its portfolio of records and information management projects. It draws on its wide-ranging field experience and extensive international network of professional contacts to assist records professionals and government stakeholders from lower-resource countries in building awareness, capacity, and effective solutions. Its projects are described on its website: <http://www.irmt.org>. All of its products can be downloaded free of charge.

ORIGINS OF THE IRMT

Between 1984 and 1988, the University of London, through the Institute of Commonwealth Studies and the Department of Information Studies, and with funding from the Leverhulme Trust, carried out an extensive field study of the management of government records across 32 countries in Africa, the Caribbean, and Asia. The aim was to identify capacity requirements as a basis for developing a relevant program of studies for international records and archives students. The study revealed a largely unrecognized but internationally significant issue—an extensive breakdown in public record keeping across the several dozen countries visited. It resulted in a new approach to educating records and archives professionals at University College London. It also led to the establishment of the IRMT in 1989 as a nonprofit vehicle for addressing the conditions that were observed.

While specific conditions varied from country to country, the overall result was the loss of control of records, and the consequences for governments were broadly similar. The study made it clear that legal and organizational structures were not in place to manage official documents, that officials could not locate the information they needed to take decisions, that vast quantities of closed records with no ongoing value were being kept in government offices at great expense, and that national history and heritage were not being protected or preserved (Fig. 1).

The study considered the causes of this situation. It reported that the countries visited lacked national strategies, policies, frameworks, and systems for managing the official records needed to support national evidentiary requirements and that the status of the records profession was low or very low in virtually all of the countries visited. Although the national archives had statutory responsibility for official records, they were isolated from the management of public administration, often playing little or no role in managing the current records that were essential for delivering government functions and protecting citizens' rights and that would one day become historical archives. Because they focused almost exclusively on the historical archives created in earlier decades, the national archives were seen as largely irrelevant to the government operations, and governments allocated them very sparse resources for delivering their work. Records professionals were not trained to tackle these challenges. The breakdown of records systems that resulted from this situation had significant consequences for governments and for citizens in terms of opportunities for fraud, corruption in procurement, a lack of evidence for protecting civil and human rights, and difficulties in managing financial and human resources.

Fig. 1 Weak records systems meant that officials could not locate the information they needed to take decisions.

Much of the IRMT's early work was focused on developing practical approaches to bringing order to the vast backlogs of unmanaged records that had built up across government agencies due to the lack of controls. Offices and corridors were piled high with stacks of records, many of them inactive. The volume was so great that it was not uncommon to find staff surrounded by piles of files, sometimes even sitting on files, or with files filling the space under their desks. Whole offices were out of use because they were crammed with inactive files. The Head of Civil Service in one country described the situation as "walking on files." Not only did it become increasingly difficult to find information needed to deliver government functions, but the situation represented a serious security risk and an open door for corruption.

The IRMT developed a methodology for bringing order to this information through hands-on workshops, where records professionals and students began the task of sorting, assessing, structuring the records, and, where it was legally appropriate, destroying paper files with no ongoing value. It also developed assessment tools and training materials geared to defining the regulatory frameworks and control systems and building the practical skills needed to establish sustainable controls.

By the mid-1990s, the rapid growth of information technology was creating an awareness of the value of information and opportunities for its use. Governments and international development planners hoped that technology would solve the information problems that had become so widespread, and international investment in computerizing government functions and improving Internet connectivity began on a large scale. Crucially, virtually no attention was given to addressing the major new challenges of capturing and preserving fragile digital information created by computerized systems as reliable evidence. As technology had an increasing impact on the way that records were created, used, and stored, the IRMT committed itself to supporting the transition from paper to digital records as the basis for delivering government operations and enabling accountability.

Over the last two decades, the trend toward digital governance has expanded steadily, with government business and communications being routinely delivered electronically, personal computers becoming the norm, large-scale computerized systems being introduced to support the management of key state functions and resources, and scanned images being regarded as an effective alternative to paper copies. The crucial function of managing the fragile digital records that were created was not recognized as an essential component of this process, and this remains a largely unrecognized risk for the delivery of the digital development agenda. Finding new means of highlighting the issues and of integrating them into digital development planning remains a central focus of the IRMT's work.

SIGNIFICANCE OF DIGITAL RECORDS AS EVIDENCE FOR GLOBAL DEVELOPMENT GOALS

The unparalleled growth of information and communications technologies (ICTs) worldwide offers tremendous new possibilities for effective governance and social inclusion. There is a new level of global awareness of the value and power of information for economic development and for eradicating extreme poverty. The Open Government Partnership is committed to the goal of making information open to citizens as the foundation for empowering civil society, with an emphasis on Right to Information and Open Data. At the same time, the UN is preparing for the Post-2015 UN Development Agenda aimed at eradicating poverty and transforming economies. In May 2013, the Report of the High-Level Panel of Eminent Persons on the Post-2015 UN Development Agenda noted, "We need a transparency revolution so citizens can see exactly where their taxes, aid and revenues from extractive industries are spent. We need governments that tackle the causes of poverty, empower people, are transparent, and permit scrutiny of their affairs."

Delivering these goals will require reliable evidence of what governments plan, do, and spend. Just as in the paper environment, in the digital environment, achieving poverty reduction, controlling corruption, building accountability and transparency, and supporting citizen engagement will require authentic and reliable records. Digital records will be needed to provide the basis for defining and delivering day-to-day operations, including budgeting, planning, monitoring, and evaluating, as well as for management controls, including regulations, standards, audits, and investigations. In the new context of openness, digital records will be essential to efforts to make information available to citizens through Right to Information/Freedom of Information or Open Data Initiatives, which will be meaningful only if reliable evidence is available and can be accessed.

At present, in the digital environment, the requirements for protecting, preserving, and making this evidence available are not in place in many countries worldwide. There is a significant risk that the evidence needed to support development goals will not be available, authentic, and trustworthy unless these risks are mitigated.

VULNERABILITY OF DIGITAL RECORDS AS EVIDENCE

Electronic media deteriorate, software changes, and hardware becomes obsolete. Valuable records and data can be difficult to retrieve after a few years or even after a few months. Digital information can easily be manipulated, deleted, fragmented, or lost, leaving critical gaps and

Fig. 2 Digital information can easily be manipulated, deleted, fragmented, or lost.

resulting in misguided policy, misdirected funding, cover-up of fraud, and weak data and statistics. Weak records systems can make it difficult if not impossible for citizens to prove unequal or unjust treatment or to challenge human rights violations. It can undermine their ability to make an informed contribution to the governance process. Laws that give citizens the right of access to government records are of little use if records are not created in the first place or cannot be found when needed (Fig. 2).

The ability to ensure that digital records are available and can be trusted depends upon having an effective records management strategy that defines the goals, principles, policies, processes, and roles needed to ensure effective and efficient use of records as evidence for governance. Records management is essentially a risk mitigation strategy that makes it possible to avoid or address gaps in the framework for managing records in relation to development goals. Defining a records management strategy is especially important for lower-resource countries, where governments continue to depend heavily on paper but are keen to introduce the benefits of information technology and open data as rapidly as possible, often with almost no capacity or resources for managing records systems. In the same way that it is vital that information security controls are in place, a records management framework is vital as a basis for achieving development goals.

The records profession, which is a coherent worldwide community of practice dedicated to protecting the availability and integrity of evidence through time and across technology change, has defined answers to the issues involved in establishing and maintaining control of records as reliable evidence. The community has reached a broad agreement on the continuum of controls required to support the capture, classification, disposition, preservation, access, and security of the records. These controls are defined in detail in international standards, which work

together to provide evidence that records are reliable and accurate. The controls cannot be achieved piecemeal but require a unified records and information governance framework. Internationally accepted records standards tend to be applied differently in different countries, but the core requirements are universal and are relevant in all regions of the world.

Many governments have not yet recognized the importance of building the framework of laws, policies, structures, standards, systems, procedures, and skills needed to capture, preserve, and make digital records accessible in a reliable form through time. Development planners often do not realize that ICT systems contain digital records but lack the full functionality needed to protect and preserve them. The growing international body of standards and good practice is largely unknown to the ICT and development environments, and it has not been adapted to meet the requirements and circumstances of lower-resource environments. These gaps need to be bridged if fragile digital records are to survive and provide essential evidence.

THE IRMT'S WORK

The IRMT is unique in its commitment to strengthening public sector records management in relation to the governance process. Its three program areas (development research, education and training, and consultancy services) work together to support this purpose. The IRMT's long-term objective is to raise international awareness of the importance of managing evidence in the digital environment and to support countries in lower-resource environments in building capacity to introduce effective and appropriate strategies for managing digital records. Drawing on its track record of success, extensive field experience, network of globally recognized experts, and close

Fig. 3 The IRMT emphasizes the importance of teamwork and capacity building.

partnerships with records professionals across the world, the IRMT works to help facilitate and share new solutions to the global challenges of managing records as evidence in the transition to the electronic environment (Fig. 3).

The IRMT's work falls into three interrelated program areas. It studies the relationship between records management and public sector management in order to define means of strengthening effective government; it develops capacity building resources that it makes freely available internationally; and it provides consultancy support to help sustainable legal and regulatory frameworks, policies, systems, procedures, and facilities. Its programs and projects are, therefore, informed by a continuous cycle of research, education and training, and the application of its findings and products in practical situations.

The IRMT has identified key elements of success in building sustainable programs for managing records as evidence, and these feature in all its projects. They include the following: linking records management directly to governance functions; taking an integrated approach to the management of records across all media from creation to destruction or long-term preservation; ensuring that all projects are practical, relevant to local circumstances, and sustainable; emphasizing the importance of teamwork; and building ownership and awareness alongside capacity.

The IRMT also recognizes the importance of working closely with key government stakeholders and with partner organizations, including professional associations, consultancy firms, academic institutions, and NGOs to define strategies, structures, and programs for managing records in support of evidence-based governance and national and international development. It also works with national archives in many countries and with a range of international organizations, particularly the International Council on Archives and its regional branches, the Association of Records Managers and Administrators International, and national bodies, such as the UK Information

and Records Management Society. It also has worked in partnership with such international bodies as the International Federation of Accountants, Transparency International, and the Commonwealth Human Rights Initiative.

Development Research

Over the last 15 years, the IRMT carried out a series of research projects aimed at understanding the relationship between records management and governance, particularly in the transition to the digital environment. The premise has been that if digital information is to provide the basis for informed decision-making, effective service delivery, and tackling corruption through increased transparency, it must be reliable and trustworthy over time. The IRMT makes its research findings available internationally, uses them as the basis for developing education and training programs, and works with governments to apply the findings practically.

The IRMT's research projects have examined the practicalities of introducing records management to support international and national development priorities, focusing on key aspects of accountability, transparency, and openness, including the Right to Information and Open Data. Since the management of money and people is fundamental to all of these issues, the IRMT has given particular attention to financial and personnel records, in both the paper-based and electronic environments. The research projects, which have run almost continuously since 1998, have included the following: *From Accounting to Accountability: Managing Accounting Records as a Strategic Resource* (1999); *Evidence-Based Governance in the Electronic Age* (2001–2004); *Integrating Records Management Requirements into Financial Management Information Systems (FMIS)* (2005–2006); *Investigating and Addressing the Requirements for Building Integrity in Public Sector Information Systems in the ICT Environment* (2006–2008); and *Aligning Records Management*

with *E-Government/ICT, Freedom of Information, and Poverty Reduction in East Africa* (2010–2011).

The IRMT also recognizes the need to monitor and measure records management frameworks, processes, and capacity in relation to the transition to the digital environment, and it draws on its research to produce assessment tools that include a gap analysis tool for assessing records management functionality in ICT systems, a high-level E-Records Readiness Tool for assessing capacity for managing electronic records and information, and a Records Management Capacity Assessment System for a more in-depth evaluation. The tools are linked to international records management standards. The IRMT is presently working to develop a Rapid Diagnostic Records Management Risk Assessment Tool.

All of the research reports and associated assessment tools can be downloaded from the IRMT's website free of charge.

Education and Training

The IRMT is committed to supporting education and training as a primary goal. Between 1996 and 2000, working with the International Council on Archives and other professional bodies, it developed the Management of Public Sector Records Study Program with the aim of helping to build core records management skills in countries where appropriate and relevant educational tools were hard to obtain. The material was intended to serve as an input to taught or distance learning courses, as a resource for conducting workshops, and as a tool for self-study. It also has provided the basis for strengthening staff capacity within local institutions. In fact, the material has been used more widely than originally expected, serving small communities across better-resourced countries, for instance, in Canada and Australia, and governments in transition, for instance, Estonia.

The study materials were distributed in hard copy to national archives and training institutions in 60 lower-resource countries with assistance from the Association of Records Managers and Administrators International. They also have been available on the IRMT's website since they were launched in 2000, with hundreds of thousands of downloads, free of charge, by educators, institutions, and individuals. The program has contributed to the development of new educational programs in countries including Uganda, Zimbabwe, Eritrea, and Tanzania. There is also a Spanish adaptation of some of the material, in two volumes, which was developed by the National Archives of Uruguay, and which also may be downloaded without charge.

The study program covers all phases of the records life cycle/continuum, as well as the application of records management principles and practices to financial, human resource, and legal and judicial records. There are about 4000 pages of training materials, including 18 teaching/

study training modules, case studies, good practice procedure manuals, and an educators' resource kit. While the material addresses public sector record-keeping issues, it can also be used in the private sector.

In 2009, the IRMT released a second set of modules that aimed to begin the process of building records management capacity in the digital environment. The material included five modules, six case studies, and a set of good practice indicators for integrating records management in ICT systems.

In 2013 and 2014, at the request of UNESCO, the IRMT collaborated with the International Council on Archives to develop a digital preservation curriculum. It provided a draft outline of the contents of the curriculum and prepared two detailed modules: *Managing Metadata to Protect the Integrity of Records* and *Understanding Digital Records Preservation Initiatives*.

Although the core issues covered by the study material have not changed, the IRMT recognizes the urgent requirement to continue developing up-to-date study material to address evolving technological requirements and goals for openness.

Consultancy Services

For two and a half decades, working with dozens of governments and dozens of international institutions around the world, the IRMT has delivered numerous projects to improve records and information management in support of governance objectives. It works with governments to help build the effective laws, policies, systems, procedures, and capacity for creating and managing trustworthy and accessible records needed to protect citizens' rights, improve services for citizens, demonstrate accountability and transparency, and protect the national historical memory. The IRMT's projects are designed to strengthen local professional capacity and build awareness of the significance of records as evidence among government officials.

The IRMT's consultancy services support both paper and electronic records systems, particularly in relation to financial management, human resource management, legal and judicial management, healthcare management, land management, decentralization, and access to information. For instance, they seek to strengthen records control systems in public financial management to reduce opportunities for fraud, corrupt procurement, and money laundering; to strengthen controls in the areas of payroll management; and to eliminate ghost workers and the retention of workers past statutory retirement age. In this way, they strengthen the Financial Information Management Systems and Human Resource Information Systems, which are trustworthy only if the information they contain is accurate.

The projects can involve addressing government-wide requirements or sector-specific needs. Some last for only a few weeks, for instance, an analysis of records

management requirements. Others are delivered over a number of years where there is a need to build a sustainable infrastructure for records management across government. Longer-term projects can include establishing appropriate legal and institutional arrangements; developing clear management responsibilities and performance criteria; drafting policies, standards, and practices; implementing new systems; and building appropriate new skills.

CONCLUSION

For 25 years the IRMT has been committed to strengthening evidence-based governance to support the goals of

improved services and resource management and to underpin accountable and transparent democracies. It has sought to build awareness of the significance of records as evidence among government officials and development planners; to support capacity building for records professionals; and to help develop innovative, appropriate, and practical solutions to records and information management problems. Most significantly, the IRMT has sought, in all of the countries where it has worked, to contribute to the well-being of citizens, whose rights and entitlements and ability to hold their governments accountable depend on the availability of accurate and reliable evidence.

International Society for Knowledge Organization (ISKO)

Ingetraut Dahlberg

Bad Koenig, Germany

Abstract

The aims, tasks, activities, and achievements of the International Society for Knowledge Organization (1989–) are presented. ISKO is that group of scholars and practitioners who feel responsible for questions pertaining to the conceptual organization and processing of knowledge, the scientific bases of which lie in knowledge drawn from the fields of logic, organization science, psychology, science theory, informatics, semiotics, linguistics, and philosophy. It aims at giving advice in the construction, perfection, and application of such organizational tools as classification systems, taxonomies, thesauri, terminologies, as well as their use for indexing purposes and thereby for the retrieval of information. Events leading up to the founding of ISKO in 1989 are described. The aims and objectives of ISKO according to its statutes are mentioned, as well as its organization, its biennial international conferences with their proceedings volumes, and the establishment of a further conference series and a textbook series. The drive and success of coordinators in establishing chapters in many countries is reviewed as well. The activities of the chapters (mainly by their own meetings and conferences) and subsequently their publications during the past years are also included. The idea and structure of ISKO's official journal—*Knowledge Organization*—is explained, and ISKO's Web site is given. Finally, the need for the Society is discussed, and its possible future is considered.

DEFINITIONS AND FORERUNNERS OF ISKO

One of the antecedents of ISKO was the establishment of the journal *International Classification* (IC) in 1974. It was edited by the entry author and published by K.G. Saur Verlag, Munich. With this journal, “classification” was understood as a multi-meaning word that includes the following concepts: 1) classification in the sense of “classification system” i.e., a system of classes arranged in hierarchical or faceted order; 2) classification in the sense of classifying, i.e., establishing a system of classes; 3) classification in the sense of classing, i.e., relating the classes of a classification system to objects or subjects of reality; and 4) classification in the sense of classification science, i.e., relating to this field of study and its activities. Another forerunner of ISKO was given by the founding of the German Classification Society on February 12, 1977, meant to study the philosophical and methodological foundations of classification and its application in many object- and subject-oriented fields of knowledge. It was chaired by the entry author from 1977 to 1986. This Society comprised members from library and information science, linguistics, philosophy, commodity science and some other sciences, and also statistics and mathematics. The non-mathematically oriented members based their understanding of knowledge on concepts as “units of knowledge” which means that any concept can be defined as a “synthesis of essential characteristics stated about any kind of a referent and needing a term or another kind of designator.”^[1,2] The mathematically oriented members of

the Society which grew from a single representative (Prof. Dr. Hans-Hermann Bock) in 1977 to almost 100 members after 12 years, did not use the conceptual approach but a formal approach to their numerically or statistically oriented understanding of classification.^[3] Thus it happened that the Society of some 200 members was dominated all in short order by the 100 mathematicians which were more strongly represented at the elections for the Executive Board in 1989. At this junction the conceptually oriented half—on the advice of Dr. Robert Fugmann—decided to leave and establish a new Society and thus, ISKO was founded on July 22, 1989. This decision had been supported by the members of the consulting editorial board of *International Classification*. In addition, it was intended to soar above the national level and to approach and include interested colleagues from other countries. At the founding meeting it was decided not to use any longer the term “classification” in the name of the new society but “Organization of Knowledge,” as this had already been used in two publications on this field of classification as titles of books by H.E. Bliss (1932/1933). To simplify the name of the new society the direct translation from the German “Wissensorganisation,” namely “Knowledge Organization” was preferred and accepted worldwide to the astonishment of its inventors. The founders of ISKO were (in alphabetical order) Dr. Ingetraut Dahlberg, Dr. Robert Fugmann, Dr. Alfred Gerstenkorn, Dipl.Bibl. Barbara Kelm, Prof. Dr. Norbert Meder, Mrs. Padmini Raj (India), Prof. Dr. Winfried Schmitz-Esser, Dipl. Vw. Ingeborg Stoltzenburg, Dipl.Ing. Rudolf Ungvary

(Hungary). Therefore three nations were represented, a necessity for the founding of an international society in Germany. Thereafter the journal *IC* became the official organ of ISKO and was renamed into *Knowledge Organization* subsequently.

AIMS AND TASKS

ISKO was conceived to function both on a national and international level as the connecting link between any and all institutions concerned with conceptual questions pertaining to the organization and processing of knowledge. It is meant to serve in assembling all colleagues, mainly from the information science fields working on problems related to the conceptual organization of knowledge, the scientific bases of which lie in the methodical knowledge from the fields of logic, organization science, psychology, science theory, informatics, semiotics, linguistics, and philosophy (particularly epistemology). According to its Statutes, ISKO has set itself the following tasks:

Awaken and support an understanding for the practical and heuristic usefulness of such an organization of knowledge, propose on a national and international level the exchange of information and experience of scientists and practitioners in this area, especially by giving advice in the construction, perfection, and application of such organization tools as classification systems, thesauri, terminologies, nomenclatures, as well as the syntactical tools going with them; observe internationally the progress made in this work; concentrate on major points of this knowledge field in special working groups, hold regular meetings in order to support these activities.^[4]

It is also stated in the Statutes that the Society will collaborate with other groupings, associations, and institutions pursuing similar aims, if in line with its goals. It aims at promoting and carrying out studies, research work, conferences and other categories of scientific cooperation, as well as disseminating knowledge for research workers, scientists, and the general public through its publications. The last sentence of its Preamble says: "Thus, responsibility and initiative to make this society their worldwide forum lies in the hands of the personal members collaborating in their concern for knowledge organization in common efforts, refraining therefore from pursuing their subjective interests and respecting the postulates of integrity and truth, mutual recognition and assistance."

ORGANIZATION

ISKO's *Executive Board* (EB) consists of seven members and one ex-officio-member, the chair of the *Scientific Advisory Council*. This latter Council has up to 21

members and advises the EB. The necessary Secretarial work of the Society is accomplished by ISKO's *General Secretary* (this is at present Dipl.Vw. H. Peter Ohly, Bonn, Germany). *Membership Assemblies* take place every 2 years together with the biennial international conferences in even years. The *President* of ISKO and its EB is elected every 4 years. *National Chapters* are founded with the help of *National Coordinators* whenever there are at least 10 ISKO members in one country. Such chapters can establish their own statutes. Their conferences should take place every odd year. They receive a small part of the general membership fee for their own expenses. Here is the list of ISKO's presidents so far: Dr. Ingetraut Dahlberg, Frankfurt (1989–1996), Prof. Hanne Albrechtsen, Copenhagen (1997–1998), Prof. Clare Beghtol, Toronto (1998–2002), Prof. Ia C. McIlwaine, London (2002–2006), Prof. Maria José Lopes Huertas, Granada (2006–). In the first years the sessions of the Executive Board were concerned among others also with the elaboration of *Bylaws to the Statutes*, such as one for the organization of Chapters and other ISKO Bodies.^[5] One Bylaw for Conferences and one for the General Secretariat had been worked on but never published. Chair of the *Scientific Advisory Council* was Prof. Dr. Winfried Schmitz-Esser (1989–2006). He was succeeded in 2006 by Alexander Sigel.

ISKO'S INTERNATIONAL CONFERENCES

After one year of existence ISKO organized its first International Conference at the Technical University of Darmstadt, Germany, August 14–17 1990, entitled *Tools for Knowledge Organization and the Human Interface*. It assembled almost 200 participants from 25 countries, 60 papers were presented, edited by Robert Fugmann and published in the new series *Advances in Knowledge Organization*.^[6] The conference in 1992 on *Cognitive Paradigms in Knowledge Organization* took place at Madras, India,^[7] the next, in 1994, was held in Copenhagen, entitled *Knowledge Organization and Quality Management*,^[8] in 1996 the fourth one, entitled *Knowledge Organization and Change*, took place at Washington, D.C.^[9] Now back to Europe, the 1998 conference, entitled *Structures and Relations in Knowledge Organization*, took place at Lille, France.^[10] The sixth conference, entitled *Dynamism and Stability in Knowledge Organization* took place at Toronto.^[11] The next one, entitled *Challenges in Knowledge Representation and Organization for the 21st Century. Integration of Knowledge across Boundaries*, took place at Granada, Spain.^[12] The eighth conference, entitled *Knowledge Organization and the Global Information Society*, took place at London, England^[13] and the ninth international ISKO conference, entitled *Knowledge Organization for a Global Learning Society*, took place at Vienna, Austria.^[14] In 2008, ISKO held its tenth

conference on *Culture and Identity in Knowledge Organization* at Montreal, Canada, August 5–8, 2008. It will hold its 11th International Conference in Rome, Febr. 23–26, 2010, its topic: *Paradigms and Conceptual Systems in Knowledge Organization* <http://www.iskoi.org/rome2010/>

HISTORICAL DEVELOPMENTS AND EARLY CHAPTER ACTIVITIES

Version 2 of a 1992 leaflet of ISKO^[15] (a version 4 was published in)^[23] gives an account of the early development of ISKO. By that time a number of coordinators were already active in the following countries: Austria (Dr. G. Budin), Brazil (Prof. Dr. Ulf Baranow), Canada (Prof. Nancy Williamson), Denmark (Mrs. Hanne Albrechtsen), France (Dr. Jacques Maniez), Hungary (Dr. Maria Domokos), Italy (Dr. Giliola Negrini), Japan (Prof. Yukio Nakamura), Nigeria (Mr. Emmanuel Adimorah), Portugal (Mrs. Ines Lopes), Russia (Dr. Eduard Sukiasyan), and Spain (Prof. Dr. Emilia Curras). International Society for Knowledge Organization Chapters have been established so far in Bulgaria (Mr. Peter Petrov), Germany (Prof. Winfried Goedert), India (Prof. Krishan Kumar), and Slovakia (Mrs. Pavla Stancikova). At this time, ISKO had about 400 members in over 40 countries. National conferences with international participation were held in 1991 in Bratislava, Slovakia (papers were published in a separate volume),^[16] Varna, Bulgaria (18 papers were published in one-page form in *Knowledge Organization* 1992, except for the papers).^[17,18] Russia's chapter held its three conferences: the first one on *Problems and Tendencies* 1993, and a second one in 1995 on *Linguistic Problems in KO*, both at Moscow. A third one was held in combination with the annual Crimean conference in 1997. Short versions of the 1993 papers were published in *Knowledge Organization*^[19] together with two papers.^[20,21] It should be mentioned, however, that the growth of ISKO in Eastern and developing countries was fostered in the years 1989–1996 by the fact that members from such countries with low incomes had to pay a rather reduced membership fee. The journal was sent to such countries in bulk and was distributed by the coordinators or chapter heads. In these years, there were about 50 ISKO members in India and some 30 members in China.

In 1993 a series of European conferences was planned on subject topics, such as Environment, Medicine, Agriculture, etc., but only one of them could be realized so far, it was the First European ISKO Conference at Bratislava, Slovakia, September 14–16, 1994 on *Environmental Knowledge Organization and Information Management*. Its 45 papers were edited by Pavla Stancikova and I. Dahlberg in another series *Knowledge Organization in Subject Areas*, Vol. 1, 1994.^[22] A further international Research Seminar on a methodological problem took place at Warsaw, September 13–15, 1995 on *Compatibility*

and *Integration of Order Systems*. Its 20 papers were edited by I. Dahlberg and Krystyna Siwek.^[23] The volume also contains an *Annotated Bibliography on Compatibility and Integration of Order Systems* by I. Dahlberg as well as the *Recommendations* of the participating ISKO members and the members of the Polish Society for Professional Information (TIP). In 1993, a series of *Textbooks for Knowledge Organization* was started with vol. 1 by Robert Fugmann: *Subject Analysis and Indexing. Theoretical Foundation and Practical Advice*.^[24] A second volume followed in 1995 by Hemalata Iyer on *Classificatory structures: Concepts, Relations and Representations*.^[25] A third volume was planned to be written by Eduard Sukiasyan on *Universal Classification Systems*. Unfortunately after 1996, these series were discontinued. From then on too—regrettably—the ISKO members of countries with low income had to discontinue their membership.

PRESENT CHAPTER ACTIVITIES

Three months after the founding of ISKO, a **German Chapter** was founded on October 6 in Frankfurt. It considers itself as successor of the non-numerical part of the *German Classification Society* (see above), although—ironically—most of the librarians stayed with the mathematicians as a section of their own, so far. Chairmen of the German Chapter since 1989 have been Prof. Winfried Goedert, Dr. Peter Jaenecke, Prof. Dr. Hans Czap, and Peter Ohly. At present there are 75 members including members from Austria, Switzerland, and the Netherlands as well as one Honorary Member, Dr. I. Dahlberg, since 2001. The proceedings volumes of the biennial conferences are available.^[26–34] In addition there exists a discussion list (wiss-org), a Web site (wiss-org@gesis.org) and an irregularly appearing newsletter. Also in pursuance of the aims of the Society, working groups had been established from the very beginning with the aim to publish results in a series called *Recommendations for Knowledge Organization*. In the interim, the work was suspended. The first recommendation was published by the WG on Content Analysis, entitled *User Evaluation of Information Systems*.^[35] Further WGs became active on University Education in KO, Cognition and KO and Universal Classification. At present new WGs are established ad hoc on demand.

Though the **Italian chapter** (chair Dr. Giliola Negrini) started its activities much earlier after the founding of ISKO, it was only in 1990 that G. Negrini arranged for a conference on *Documentary Languages and Databases* in Rome, December 1990. Although it was not co-organized by ISKO, but held in the spirit of ISKO, therefore its proceedings volume was included in the series *Advances in Knowledge Organization*.^[36] In an e-mail of November 20, 2007, Claudio Gnoli reported: “On the initiative of Giliola

Negrini (National Research Council), who collaborated with Dahlberg applying her Systematifier model to documentation in various sectors and organized four scientific events in Rome with printed proceedings “(see bibliography^[37–39]). In 2004, coordination was taken over by Claudio Gnoli (University of Pavia), and a national chapter was formed, currently including about 25 people and some institutions. The chapter organized annual meetings at Milan Bicocca University, as well as specialized events on the organization of local knowledge and of philosophical knowledge, all with online proceedings (<http://www.iskoi.org>). Several research projects are active within the chapter, including integrative level classification (<http://www.iskoi.org/ilc/>), relations between object and bibliographic classifications (<http://www.iskoi.org/bagpipes/>) and cooperation with GRIS (Subject Indexing Research Group).”

In **Spain**, Prof. Dr. Emilia Curras organized in 1992 the first ISKO Meeting in combination with a meeting of FID/CR, the Classification Research Committee of the Federation Internationale de Documentation. A year later, the Spanish Chapter was formed and a conference was held in November 1993 on *Knowledge Organization in Documentary Systems*, with the support of Profs. Javier Garcia Marco, Miguel Angel Esteban, and Rosa San Segundo. Subsequently, J. Garcia Marco started a journal called *Scire, Knowledge Representation and Organization*, appearing twice a year with a scientific board and peer-reviewed contributions. He published in it the papers from this and later conferences. A second ISKO-Spain national congress took place in 1995 and a third one in 1997, all these conferences took place in Madrid.^[40–42] In 1998 the Chair of ISKO Spain went to Prof. M.J. Lopez-Huertas. The proceedings’ volumes of the next four conferences are available.^[43–46] From 2007 on, the Chair of ISKO Spain went to Prof. Rosa San Segundo.

The **Polish ISKO Chapter** started from the participation of Polish colleagues in the First European ISKO Conference on Subject Areas (see above), held at Bratislava 1994. A year later, the ISKO-TIP Research Seminar on Compatibility and Integration of Order Systems was held in Warsaw, which helped to bring the interested colleagues together from the whole country. It was, however, not until 2006 that a new Polish coordinator was elected, Prof. Wieslaw Babik from the Institute of Information and Library Science of the Jagiellonian University in Cracow, that the former Polish ISKO members were reassembled and newcomers added so that a group of 23 members was formed and the National ISKO Chapter could start its work in 2007. A plan for a number of activities for the years 2006–2010 is being proposed. It organized panels on *What is knowledge organization?* at Cracow and Katowice in June 2007 and also a Session during the 9th Forum of the Polish Society for Scientific Information in Zakopane (September 25–28, 2007) entitled: *The role of knowledge organization in information exchange and development of professional information services for education, science*

and culture for the knowledge society. Information on the Polish ISKO activities were published in two renowned Polish scientific journals and Web sites were designed and created. Twice a year an electronic bulletin *ISKO in Poland News* is issued.

The **French ISKO Chapter** was established after the Warsaw Research Seminar of 1995. Before that time, Prof. Jacques Maniez was ISKO Coordinator for France, however the participation of Mrs. Danièle Degez in Warsaw helped to assemble existing French ISKO members and to form the Chapter in 1996. Dr. Widad Mustafa el Hadi who had already attended the first International Conference of ISKO, Darmstadt 1990, was elected Chairperson, Danièle Degez as Deputy Chair, and Jacques Maniez as Treasurer. In November 2000, the French chapter was granted the nonprofit legal organization status. Since that time, ISKO France organized biennial conferences, known as Journées ISKO-France. The first one took place in Lille, 1997.^[41] Until 2007, six biennial conferences have taken place. They are now called *ISKO-France Conferences*. Their topics and venues were as follows: *Indexing in the Era of the Internet* (Lyon); *Information Filtering and Automatic Summarization in Networks* (Paris); *Knowledge Organization Conceptual Approaches* (Grenoble); *Knowledge Organization and User-Oriented Strategic Watch Information Systems* (Nancy); *Knowledge Organization in the Information Society* (Toulouse). The proceedings volumes are available.^[47–52] Chairpersons of ISKO-France were Dr. Widad Mustafa el Hadi (1996–1999), Prof. Dr. Jean-Paul Metzger, (1999–2005), and Prof. Dr. Stéphane Chaudiron, University of Lille (2005, reelected 2007). In June 2006 the French ISKO Chapter coorganized *La Semaine de la Connaissance*. This “*Knowledge Week*” gathered all French Societies concerned with knowledge and linguistic issues.

In **England**, Dr. Steve Pollitt had been active as coordinator ever since 1994, but unfortunately a serious illness lead to his early death. Much later, the **British ISKO Chapter** finally was planned in London, on February 7, 2007, in a preliminary meeting hosted by John Lindsay at Kingston University. A Web site was designed and an invitation to join ISKO UK was widely disseminated. Its inaugural meeting was held on March 26, 2007. Vanda Broughton, lecturer in the School of Library, Archive, and Information Studies (University College London) was voted chair, Bob Bater, a consultant in the field of knowledge organization was elected Vice-Chair, and Aida Slavic as Treasurer. Mrs. Broughton wrote:

Starting with ten members, the chapter quadrupled its membership by December 2007, attracting an interesting mixture of academics, researchers, information consultants and practitioners in equal parts. Membership at the end of 2007 stands at 42, including two honorary members, Brian Vickery and Jean Aitchison, pioneers in knowledge organization in the United Kingdom. The

popularization of ISKO in the United Kingdom was achieved through a series of London meetings organized around topics of interest. One type of meeting organized under the banner 'KOnnecting KOMmunities' was held in May with the expressed purpose of providing a forum for knowledge managers and taxonomists in nonacademic sectors. This gave us an opportunity to share experiences and interests in a formal discussion, followed by the opportunity for social networking. It was very apparent that KO practitioners in industry and government suffer from relative isolation and greatly welcomed the opportunity to meet and exchange views with others. The second, September meeting, entitled *Tools for knowledge organization today*, was a half-day themed conference, consisting of three talks on the subject of knowledge organization standards and was attended by an audience of over 50. The third was another KOnnecting KOMmunities meeting under the heading *Ranganathan revisited: Facets for the future* with two talks from the academic and research point of view on facet analysis, and three presentations of information organization and retrieval solutions based on facet analysis. This meeting was attended by more than 80 people. Further meetings are planned for 2008. The first ISKO U.K. biennial conference will be held in 2009.

The **Indian ISKO Chapter** was established right after the first ISKO Conference in Darmstadt at which a number of Indians were present, among them Dr. Mohinder Satija, GND University, Amritsar, who became India's ISKO Coordinator and Prof. Krishan Kumar, University of New Delhi, who took over the Chair of ISKO India. On January 7, 1994, an ISKO Seminar was held in Bangalore together with the DRTC and the Institute of Information Studies. A report by Mr. Sukhdev Singh and Dr. K.N. Prasad on the four papers given was published in ISKO News 16.^[53] In 2005 coordinatorship went to Prof. K.S. Raghavan, DRTC Bangalore, and Prof. A. Neelameghan became its president. As of December 6, India has 21 ISKO members. Recently, in September 2007, DRTC in association with ISKO and some other institutions organized an international conference on *the Future of Knowledge Organization in the Networked Environment* (IKONE 2007). Papers were published in a preconference volume, edited by K.S. Raghavan.^[54] He wrote that the biggest challenges in the next 5 years would be: to build KO schemes and hide them from the user; to design and implement education and development in KO; to understand "human needs" and what these needs are derived from; what are the factors that influence the mental reference model? And finally, to build methodologies for KO. At present the following three research projects are being pursued: Revision of Colon Classification; A bilingual thesaurus for classical Tamil Studies; and Work on defining, categorizing, and developing a taxonomy of lateral relationships, including multilingual multicultural contexts.

The **Brazilian ISKO Chapter** was officially created on October 31, 2007. It has now 34 members, all of them are

PhDs and act as professors and researchers in the KO branch. It is officially located at the Department of Information Science of Sao Paulo State University (UNESP) in Marilia—Sao Paulo. Its President is José Augusto Chaves Guimaraes. He wrote that the first congress of the Brazilian ISKO Chapter will take place in Joao Pessoa, Brazil, in October 2009. He outlined the major research themes of his Chapter as follows: Epistemological foundations of KO; Interdisciplinary dimensions of KO; Terminological tools in KO; KO and cultural memory; KO and domain analysis; Technological background of KO; Social aspects of KO (education, professional acting, ethics, etc.) and he mentioned that the Brazilian ISKO Chapter is deeply attached to the Working Group 2—Knowledge Organization and Representation—of the Brazilian Information Science Research Society (<http://www.anci.org>).

ISKO's Nordic Chapter was founded on November 8, 2007 in Copenhagen. It covers Sweden, Denmark, Norway, Finland, Iceland, and the Faroe Islands. Its Chair is held by Mikkel Christoffersen with Birger Hjørland (DK), Hanne Albrechtsen (DK), and Per Nystroem (SWE) on the Board. So far, 22 people have expressed interest in the chapter. A Web presence will be established soon and a conference is being planned in Sweden in 2009.

ISKO's U.S. Chapter had been planned to be established in 1994 at a conference in Urbana Ill., organized by Prof. Pauline Atherton. Prof. Hemalata Iyer from the University of Albany had been the coordinator and had invited her colleagues in the United States. However, the strong voice of one person present at that meeting (which I attended too) sufficed to prevent the chapter from realization. Recently, Prof. Richard P. Smiraglia wrote^[55] that at the 2007 *North American Symposium on Knowledge Organization* (convened at the University of Toronto, a general assembly voted for the creation of the **North American Chapter of ISKO**. A standing committee will bring forth bylaws and organize a second symposium for the summer of 2009. He also gave a survey on the papers of this Symposium and indicated that 13 of the papers can be found in the Web. It should be mentioned that Prof. Nancy Williamson of the University of Toronto had been active as ISKO Coordinator of Canada since the early 1990s and assembled around her the Canadian ISKO members, although an official Chapter had never been created there. She is well known to the ISKO community for her many excellent reports in our journal, also on the international ISKO conferences. At the ISKO Conference in Vienna, 2006, therefore, she was elected second Honorary ISKO member.

THE JOURNAL KNOWLEDGE ORGANIZATION

As stated above, this journal was started in 1974 as *International Classification*. It appeared in the first years only twice a year, later on three times and became a quarterly from 1980 onward. The journal is "devoted to Concept

Theory, Classification, Indexing, and Knowledge Representation.” It contains a section for articles, for reports, for news in the field of classification/knowledge organization, book reviews, and a current bibliography in systematic order with an author index. From 1974 to 1996 all sections were edited and compiled by I. Dahlberg. From 1997 to 1998 it was edited by Charles Gilreath, Florida with Hanne Albrechtsen for ISKO News, Werner Bies for Book Reviews and Gerhard Riesthuis for the current bibliography. In 1999 it was edited by Clare Beghtol, from 2000 to 2004 by Hope Olson and from 2004 on by Richard Smiraglia. In the meantime, the ISKO News Section was dropped because of the ISKO Web site, but resumed by Hanne Albrechtsen in 2007. The book editor W. Bies was succeeded by Michèle Hudon and later-on by Clément Arsenault. The bibliography section of G. Riesthuis was—after his very helpful work from 1997 to 2006—succeeded by I.C. McIlwaine. The issue 1999/4 contains a systematically arranged bibliography of all ISKO publications of the past 10 years, compiled by Gerhard Riesthuis with the help of Winfried Schmitz-Esser. It comprises altogether 1148 titles from proceedings volumes, as well as from the journal. The Classification System for Knowledge Organization Literature, according to which the titles have been arranged, is placed on pages 192–201, followed by the outline of the Information Coding Classification. An author index has been added. Unfortunately there were severe backlogs during the years since 1999 due to the fact that the designated editor (after Ch. Gilreath) could not start his work immediately and gave up finally because of health reasons. Prof. Smiraglia’s diligence succeeded in having it on schedule again by 2008. His own sincere interest in this field has given the journal a new attraction, especially by his editorial of the last issue of 2005 with his question: “What exactly is knowledge organization?”^[56] A kind of an answer was meant to be provided by the article in the next issue (2006/1) *Knowledge Organization: A New Science?*^[57] which also tries to outline future tasks of this new (old) science (see the section “An Age-Old Activity and Its Future Possibilities”).

THE ISKO WEB SITE

The ISKO Web site is <http://www.isko.org/contact.html>. Under this address one will find the following entries: About ISKO, Join ISKO, *Knowledge Organization* journal, ISKO Events, ISKO Chapters, ISKO People, ISKO Publications, and Contact us.

AN AGE-OLD ACTIVITY AND ITS FUTURE POSSIBILITIES

The huge volume in which the Russian scholar, Eugen Shamurin^[58] described the past 3000 years of attempts to

develop instruments for the ordered collection of written material shows an interesting development from rather primitive lists of terms over elaborated schedules in the middle ages and the later centuries until the many classification schemes of the nineteenth century, of which some are still in use today, like the *Dewey Decimal Classification* and its younger offspring, the *Universal Decimal Classification* since in many revised editions. In the twentieth century, the Indian mathematician and librarian S. R. Ranganathan (1892–1972) enriched the field of classification with numerous new ideas, as well as practical advices especially by categorization of concepts—his so-called facet analysis—well described in his *Prolegomena to Library Classification* of 1967.^[59] His ideas were taken up by the British Classification Research Group already in 1959 and used in the elaboration of many special classification systems, as well as for the revision of the *Bliss Classification*. In Germany, the biologist Martin Scheele used the same approach for the organization of knowledge in biology^[60] and the author of this entry used it for the construction of an entirely new universal system, her fully faceted *Information Coding Classification*,^[61] which is not based on disciplines, as all the other universal systems, but on general objects of reality, having by this an ontological basis as described in Dahlberg^[62] and Dahlberg^[63] The essential new aspect governing ISKO and its adherents are the possibilities lying in the more exact ways of system building by concept analysis. As it was said above, a concept is a knowledge unit because it refers with its concept elements (characteristics) to the necessary properties which can be stated on a referent. Thus, the characteristics resulting from such statements are the (knowledge) elements which create the relationships between concepts (identity, similarity) and can be used for system and structure building. Already Linné had known this who constructed his ingenious schemes for animals and plants on their anatomic properties. From all of this, it should also be understood, that knowledge organization differs essentially from knowledge management, see the critical remarks by J. Essers and J. Schreine.^[64] See also work by Kasten.^[65]

We are confronted today in the Internet search engines with the difficulty of retrieving information just by names and terms without considering their conceptual relationships. Any approach ignoring and failing to use the indispensable conceptually linked methodology will go astray and engross the jungle of “knowledge” in the Web or in his/her own files. But it is very hard to convince newcomers of the need for conceptual interrelationships. Millions of dollars have been wasted already for projects of people who think that computers can do automatic indexing. R. Fugmann has shown this very clearly^[66] long ago. A paragon of systematic and definition-based organization of concepts is the UMLS, the Unified Medical Language System of the National Library of Medicine in Bethesda, Maryland. It should hopefully serve as a model for the elaboration of concept systems of other subject fields as well.

Apart from this, the tasks of today, for which ISKO stands, should be seen in the collaboration of classificationists with terminologists and experts from the subject fields in question, in order to elaborate in possible future *Institutes for Knowledge Organization* the concept systems for each known subject field and area. This then would result in the necessary order of our concepts and their terms which can be visualized in adequate schemes and used to the benefit of all those who need to understand the relationships which link up human knowledge to a whole. Any single item in isolation, i.e., without its connection to other items cannot be understood, this has already been stated by the German theologian and philosopher Paul Tillich.^[67] But the systematization of concepts is not an easy job, as Dagobert Soergel had stated in his first book of 1969 that "systematizing knowledge should occupy the same scientific rank as any original research work."^[68] It is therefore hoped that such a new approach to our age-old science of classification should now be recognized and taken up as an absolute necessity for the organization of our knowledge and the subsequent understanding of what we actually know.

ACKNOWLEDGMENTS

I herewith thank the coordinators and chapter heads of the countries Italy, Russia, Spain, India, France, Poland, England, Brazil, and Scandinavia for their helpful answers included in this entry, as well as the ISKO General Secretary, Mr. H. Peter Ohly, who provided me with further information.

Internet Genres

Kevin Crowston

School of Information Studies, Syracuse University, Syracuse, New York, U.S.A.

Abstract

Rhetoricians since Aristotle have attempted to classify communications or documents into categories or “genres” with similar form, topic, or purpose. This entry surveys research on genre as it relates to Internet documents. The entry briefly presents the concept of genre in general, and then reviews the evolution and emergence of genres on the Internet. It concludes with an examination of the possible use of genre for improving information access on the Internet, with specific discussion of the issues in developing taxonomies of genre and automatically recognizing document genre.

INTRODUCTION

Rhetoricians since Aristotle have attempted to classify documents into categories or “genres” with similar form, topic, or purpose. (In this entry, we adopt a broad definition of document as “signifying objects,”^[1] meaning something that serves as evidence, regardless of the particular medium or form.) Numerous definitions of genre have been debated in the applied linguistics community,^[2,3–7] while other groups have struggled with similar notions, such as discourse or document types, for example, in SGML.^[8] This entry, for example, is an instance of the *encyclopedia article* genre, commonly used to communicate the state of knowledge in a field. Other common genres include *letters* and *memos*, *project team meetings*, and *TV sitcoms*, all immediately recognizable by their typical purpose and characteristic form. In this entry, we provide a brief review of the concept of genre in general, drawing primarily on the cultural perspective of the New Rhetoric school,^[4,9] before addressing the theory and applications of genre for digital documents found on the Internet.

Genres define classes of similar documents. Such a categorization can be made on different bases and approaches to defining genre have focused on different aspects of documents (see Breure^[10] for a review of the development of the concept). Some genres are defined primarily in terms of the physical form, such as a *booklet* or *brochure*; still others in terms of the document form, such as *lists* or *directories*; while other genres are defined by purpose or function, such as a *proposal* or *inquiry*. However, most genres imply a combination of purpose and form,^[2] such as a *newsletter*, which communicates “the news of the day,” including multiple short articles and is distributed periodically to subscribers or members of an organization.

There is a close relation between the terms “genre” and “text type.” Lee^[11] distinguished between them by

suggesting that the term “genre” is often used for definitions based on external criteria, such as purpose, while “text type” is used for definitions based on internal criteria, such as form, but goes on to conclude that genre can be used “to describe most of the corpus categories we have seen.” (Moessner^[12] makes the same distinction.) For the purpose of this entry, we will use the term genre as including aspects of both form and purpose.

Campbell and Jamieson^[2] suggested that genres arise as responses to recurrent communicative situations. Given a recognized need to communicate (i.e., a purpose^[13]), individuals will typically express similar social motives, themes, and topics in a communication with similar physical and linguistic characteristics (i.e., form), that is, they will communicate in a recognized genre. Miller^[6] argued that the situations that give rise to the use of genres are social situations and that the process of creating genre is one of typification, as similarities in situations are recognized. If the typification is useful, the use of the genre becomes routine. She further argued that genres must accomplish a recognized social function and criticized the labeling of *environmental impact statements* as a genre because they did not meet this criterion, but rather had multiple conflicting motives.

Swales^[7] similarly viewed genres as “a system for accomplishing social purposes by verbal means.” He suggested analyzing documents in terms of their exhibited characteristic moves, defined as “a functional unit, used for some identifiable rhetorical purpose.”^[14] For example, Swales^[7] analyzed the *introduction*, *methods*, *results*, *discussion*, and *conclusion sections* of research articles as well as briefly touching on other research process genres, such as *abstracts*, *presentation*, *theses*, and *grant proposals*. Following Swales’s^[7] approach, researchers have described other scientific genres such as *research paper abstracts*,^[15] and *discussion sections*,^[16] *grant proposals*,^[14] *posters*,^[17] and other *visual presentations at scientific meetings*^[18] and *French thesis defences*.^[19]

Researchers have examined as well as journalistic genres such as *news*,^[20,21] *editorial letters*,^[22] and *magazine covers*,^[23] and genres from the commercial world, such as *business letters of negotiation*,^[24] *letters of application for jobs*,^[25] *Chinese sales letters*,^[26] *environmental impact statements*,^[27] *building reviews*,^[28] and *philanthropic direct mail*.^[29]

THEORY: DOCUMENTS AND GENRE

Viewed from the perspective of the reader of a document, identification of a document's genre makes the document more easily recognizable and understandable, thus reducing the cognitive load of processing it.^[30] Because we drew on the *encyclopedia article* genre in writing this entry, for example, a reader should be able to more quickly determine the purpose and content of our communication and begin to evaluate its contribution. The form of the article gives hints to its meaning and appropriate uses. Similarly, following the form of the genre of a *research article*, *letter of application*, *parking ticket*, or *bank statement* makes the corresponding documents easier to recognize, to assess, and to use. This effect has been demonstrated experimentally: Vaughan and Dillon^[31] found that readers of a Web newspaper that followed genre conventions reported better comprehension, usability, and ease of navigation than readers of a purported newspaper that did not. Knowledge of genres can similarly help creators of documents by providing a known form for achieving a communicative purpose. Rather than having to innovate in all aspects of a document, a writer can reuse the form of a familiar genre to achieve their purpose. Teaching of genres is thus seen as an important aspect of teaching language and communication, for example, in elementary,^[32] second language,^[33] and English for Special Purposes^[34] education.

In addition to helping senders and recipients singly, knowledge of genres can also facilitate interaction, since multiple communications may be performed in a recognizable pattern, what Bazerman^[35] called a "genre system." In other words, recognizing that a communication is of a particular genre may suggest the form expected for the reply. Swales^[36] similarly defined a "genre chain" as a sequence of documents of different genres on a given topic. Examples include the sequence of *examination* and *cross-examination* in a trial, or the cycle of *article submission* to a journal or conference, *reviews*, *final acceptance* or *rejection letters* and publication. In each case, knowledge of the genre system provides information about how to proceed with the interaction. For example, Tardy^[37] examined the genre system of research funding, identifying an interlocking set of genres such as a *research agency's mission statement* and *program information*, *informal meetings with program officers*, *applications*, *panel reviews*, and *decisions*. Antunes, Costas, and

Dias^[38] analyzed genres related to electronic meetings. Features of a genre may enable their use in a genre system: for example, page numbers in a *technical paper* make it possible to more precisely cite concepts or quotations from the paper, thus binding the paper into the literature.

For genres to be of aid in communication though, they must be shared across the members of particular discourse communities.^[7] Thus, genres are socially situated. Teachers and rhetoricians have acknowledged that learning about genres, and through genres, is learning how to participate in a community (e.g., Chapman, M.L.^[32]). On the other hand, a genre may be unfamiliar or hard to understand for someone outside of the community. In fact, recognition of a particular genre is one sign of membership in a particular community (one needs only to witness the uncritical citing habits of college students who are not able to distinguish a popular Web genre from a serious scholarly one). Indeed, Freedman and Medway^[39] suggest that incomprehensible genres may even be used deliberately to defend positions of privilege. Thus genres are not only a type of discourse but are themselves embodiments of social or communicative events.^[40]

Leveraging the situated character of genres, Yates and Orlikowski^[41,42] proposed using them as a lens into organizational practices. Studying organizational discourse as examples of genres, anchors, and situates the investigation in a way that other approaches could not because each genre has within it the information for how it should be interpreted within a particular discourse community. For example, Yates, Orlikowski, and Okamura^[43] contrasted the explicit and implicit structuring of genres in the introduction of a new communications system, and Schryer and Spoel^[44] examined genres as a way to understand professional identity formation of medical students and of midwives.

To capture these social elements, Orlikowski and Yates^[42] introduced the notion of a "genre repertoire," that is, the set of genres in use within a community. They noted that different communities use different genres in their communication, and use common genres with different frequencies. (Hengst and Miller^[45] refer to this situation as the "pervasive heterogeneity" of genres). These differences provide one source of insight into the communicative (and other) practices of the community. For example, a community of social scientists and computer scientists can be distinguished by the frequency of use of different paper genres, as well as the paucity of computer programs and program documentation created in the former, reflecting different modes of research.

Of course, the reality of documents and genre is not as clear-cut as the theory above suggests. First, not all communications or documents are necessarily generic. For example, Swales^[7] ruled out conversation as a genre, arguing that the concept only applies to completed texts. Pieces of text or unfinished texts may not be generic. As well, if genres are formed in response to recurrent

communicative needs, then communications in novel (or even relatively novel) situations may also not be generic. This circumstance may describe large portions of the communication taking place via the Internet (and so of the documents found there). Even in typified circumstances, an author may deliberately or inadvertently fail to reproduce the necessary form of a genre, again producing a non-generic document. Finally, the relation amongst genres in a genre system is rarely linear; in any given situation, there may be a set of appropriate responses.^[34]

Furthermore, the boundaries between genres are often fuzzy and documents may show considerable variation in form even within a genre.^[12,46] As a result, it may be helpful to think of genres defined by exemplars and documents as being more or less good examples of a genre rather than attempting to draw firm boundaries. As well, as Orlikowski and Yates^[42] point out, some communications use multiple genres simultaneously, such as a *proposal* embedded in a *memo* or a *book chapter* in a *book*, along with *table of contents* or *index*. Other documents might have some mixed attributes, e.g., *bibliography* that is also an *index to a document collection*. As a result, the mapping of documents to genre may be one to many. This mixing of genres is likely to be particularly problematic for digital documents, which can have multiple forms of presentation.

Further complicating the study of genre is the fact that knowledge of genres tends to be quite tacit and situated in use. Being able to recognize or use a genre is typically knowing “how to go on”^[47] in a particular situation rather than formal articulable knowledge. The genre analyses cited above are research contributions precisely because they required research to uncover the hidden regularities in the documents. In practice, an individual may recognize and be able to use a document, while being unable to articulate a name for its particular genre or to say how they know what it is or which particular features are important for defining the form. When tested out of context, users may find genre hard to apply. For example, Santini^[48] had 135 users to classify the genre of 25 Web pages and found high levels of agreement on only a handful of documents, while others attracted as many as four equally popular labels. Similarly, in a study with 102 Web pages, Rosso^[49] found a wide variety of genre terms^[49] when three users were asked to pick their own labels. On the other hand, in a study with 257 users and 55 pages, he obtained a reasonable level of agreement (70%) when the choice was restricted to one of 18 terms, again suggesting that genre can be recognized more easily than produced.

INTERNET GENRES

We now turn our focus to genres of digital documents found on the Internet. The Internet and in particular the World Wide Web provides a particularly interesting

setting in which to study the use and development of genres for several reasons. First, the capabilities of the new medium have led to the development of many new genres of communication. Space limitations preclude a comprehensive review of the development of the Internet from the Advanced Research Project Agency Network’s (ARPAnet’s) four computers in 1969 to the immense and nearly ubiquitous network of today, but we note that the increased functionality of the Internet has been paralleled by an explosion in Internet genres. In particular, the technology of the Web extends the notion of a document—and thus the notion of genre—because Web pages can provide functionality in addition to information. Indeed, some Web pages are more comparable to computer interfaces than to conventional paper documents. As a result, functionality may be important in understanding genres on the Internet. Furthermore, the rapid development of this medium suggests a high level of experimentation with potential genres. Bearman,^[50] for examples, notes the rapid evolution in what he refers to as “forms of material” in electronic media in general.

Second, since many Web sites are open to the public, many examples of Web communication are easily available for study. Furthermore, because there is no central management of the Internet or the Web, there is no explicit management or enforcement of genres of communication, as might happen in the introduction of a communication system in a corporate environment.^[51] Instead, individual Web developers individually choose how to present their information, drawing on their understanding as members of a community, what Orlikowski et al.^[51] called implicit structuring (in this case, from the point of view of the Web page developer rather than the recipient of the communication). Yates and Sumner refer to the “democratization of genre production” as “communities evolve increasingly well-defined genres to better support their particular communicative needs and work practices.”^[52] However, even in this free-for-all, mutual acceptance of genre is important to enable communications. Yates and Sumner^[52] argue that on the Web, genres help in both the production and consumption of documents because genre adds “fixity” in a medium that does not otherwise distinguish very well between text types (say, a *book* and a *post-it*).

Finally, there are many communities meeting on the Web, bringing experiences with different genres and using the Web for many different purposes. The Web is sometimes used for direct communication where someone with a Web server “delivers” a document to members of a known community by giving them a URL. For example, some academics use the Web to communicate with colleagues by publishing their own papers, and with students by publishing syllabi and assignments. Another example of communication within a predictable community is computer companies announcing new products, publishing catalogs, or providing troubleshooting tips online for

their customers. However, in many other cases the audience is unpredictable. Unlike the Usenet or electronic mail groups, there is no clear separation of communities into different channels of communication (as is the case for journals or talks given at conferences, for which the audience is likely to have shared interests).

Indeed, it seems a stretch to say that there is a single Web community at all. Instead, the genre repertoire reflected in a collection of Web pages will be the result of interactions within and among multiple communities. In some cases, a genre may act as a type of boundary object,^[53] providing a common point of contact between different groups.^[39] In others, this mixing may lead to genre confusion, meaning that there is a practical need to understand the way genres enable communication. For example, organizations have used the Web to publish information such as *product brochures*, *annual reports*, *country, state, and city home pages*, *government agency press releases*, etc. These organizations tend to use familiar genres when putting information on the Web. However, a person happening to reach a document on one of their Web sites has a good chance of being outside the community in which that genre evolved. As a result the document may be confusing and the communicative purpose lost.

Evolution of Genres

To understand the evolution of genres on the Web, we draw on studies of how predigital genres have evolved over time. Drawing on Giddens^[47] structuration theory, Orlikowski and Yates^[42] argued that, "People produce, reproduce and change genres through a process of structuring." As members of the community draw on their knowledge of a genre repertoire to communicate, they reinforce the use of these genres, making them more appropriate or legitimate for use in the given situation. For example, by creating an order entry Web page that draws on the genre of a paper order form, a designer reinforces the appropriateness of the order form genre for this type of communication, making its use in future situations more likely. In other words, the set of genres in use (i.e., the genre repertoire) is both a product of and a shaper of the communicative practices of a community.

Orlikowski and Yates^[42] suggested that in a new situation (such as in the introduction of a new medium such as the Internet) individuals will typically draw on their existing genre repertoires, reproducing genres they have experienced as members of other communities. For example, Görlach^[46] notes the emergence of new genres, such as the *cooking recipe*, that draw on early genres, in this case the *medical recipe* (though he uses the term text type rather than genre). However, people are also free to modify a genre and communicate in a way that invokes only some of the expected aspects of a form. If these changes become repeatedly used (i.e., typified), they too may

become accepted and used together with or instead of existing genres, thus extending or altering the genre repertoire. Because the definition of genre relies on social acceptance, it is impossible to define the exact point at which a new genre emerges from the old one. Acceptance may take many years. However, after some period of coexistence, the new combination of form and purpose may become generally recognized and even named as a separate genre. As well, genres may be accepted in different communities at different rates. The emergence of distinctive new genres would be one sign of the formation of a new community with new communicative practices.

Take, for example, the *academic journal article*, a distinctive genre with the communicative goal of reporting research results and establishing a researcher's credentials and reputation. Journal articles have moved nearly intact to the Web and can be found in many online databases and on publishers' Web sites as well as, on the Web sites of individual authors. These documents are often identical to the paper versions, an example of a reproduced genre (literally reproduced, as in many cases, the Web versions are simple scans of the paper form). However, in a few cases, the form of the journal article has begun to change to take advantage of the possibilities of linking or embedding information. For example, citations in papers may be hyperlinks to the referenced articles. In part to enable easier searching of results, some journals now require *structured abstracts*, a particular genre of *abstract* with a distinctive form. Some publisher sites allow users to comment on papers, enabling more interactive follow-up discussion. Such documents are examples of adapted genres. Even more interesting is the emergence of forms other than journal articles for reporting research results, such as *datasets*, *software*, or other products of research, all examples of emergent genres. For example, researchers in genetics may publish *gene sequences* in a variety of specialized databases that can substitute in some case for a journal publication.^[54] Similar efforts are underway in other disciplines, meaning that the eventual form used for reporting research may bear only passing resemblance to the self-contained 20- to 25- page articles of today.

Related changes are already visible at the level of *journals*. For example, while paper journals are often reproduced on a Web site, there are now journals that publish only online editions, which need not conform to typical page limits or even have volumes at all (an adapted genre). There are suggestions that the increased use of online databases for finding articles (either by topical search or citation indexing), as opposed to subscribing to a handful of specific journals, is blurring previously distinct publications into "the literature."^[55] As a result, the need for individual journals with distinct missions and readerships may be reduced, as is the utility of the genre itself. Similarly, the widespread use of *working paper* archives and of general search engines that cover such "grey literature" (*working papers*, *conference papers*,

etc.) may blur the boundary between these genres and journal articles and thus lead to hybrid or novel genres. (Indeed, such a shift may have already happened in disciplines that value *conference papers* on par with *journal articles*, reducing the distinction between the purposes of these genres).

These emergent genres may be immediately accepted or, more likely, there may be a transition period during which the limits of the genre are renegotiated. For example, the *electronically distributed journal article* is still in transition.^[56,57] It is being used, but this adapted genre is not yet completely accepted or considered legitimate for all purposes (e.g., as evidence for a tenure case) by the academic community as a whole. As well, modifications of genres that are parts of genre systems may require corresponding changes to the rest of the system. For example, changes in citation habits will be necessary before page numbers can be dropped from the *technical paper* genre. Such interdependencies between genres will tend to slow the adoption of a new genre.

Internet Genres

While many genres have been reproduced more-or-less faithfully, as in the example of *journal articles*, the Internet has seen the rise of a few novel genres. In a study of 1000 Web documents, Crowston and Williams^[58] were able to identify documents of many familiar genres and of a few genres that seemed to be new to the Web, such as the *hotlist*. A specific example of a novel genre is the *home page*. As early as 1996, Furuta and Marshall^[59] noted the emergence of this genre as a result of the specific affordances of the Internet. While Bates and Lu in 1997 suggested that the *home page* genre was still inchoate,^[60] soon after Dillon and Gushrowski^[61] found that the features of *personal home pages* seemed to have stabilized rather quickly. The *Frequently Asked Questions (FAQ)* document emerged as a distinct genre on the Usenet and was then translated to the Web. An AltaVista search done by Crowston and Williams^[58] indicated approximately 170,000 Web pages with FAQ in their title (a search in 2007 with Google finds more than 16 million such pages).

Other authors have identified a variety of Internet specific genres. Some have to do with particular communications media used on the Internet, such as *e-mail message* or *Weblogs*. Gains^[62] analyzed small collections of *business* and *academic e-mail messages*. He suggested that e-mail as a whole has too many uses to be considered one genre and that the business e-mails analyzed “appear to follow the normal conventions for standard written business English,” suggesting that they did not include new genres. On the other hand, he noted that *academic e-mail messages* had some conversational features and suggested that the collection might include new genres of communications. Gruber^[63] analyzed contributions to two *academic mailing lists* as forming a single genre with

features of *academic letters* and *scholarly publication* as well as of oral communication. (It should be noted that these analyses were carried out when the medium was still novel to many users.) More recently, Barron^[64] analyzed the properties of *unsolicited commercial e-mail* (UCE or “spam”). She noted similarities between *spam* and other promotional genres, with moves such as capturing attention, establishing credentials, introducing the offer, and multiple moves soliciting a response. She noted differences though, such as the need to capture attention to get the message opened and the inclusion of offers to unsubscribe the recipient.

A more recent innovation is the *Weblog* or *blog*. Based on an analysis of a random sample of 203 blogs, Herring et al.^[65] characterized *blogs* as a “hybrid genre that draws from multiple sources” both off-line and Internet. They distinguished several types of *blogs* with different forms and purposes as well as distinct origins. They characterized most of their samples as *journal blogs*, which they suggested draw on the form and purpose of *diaries*, since they report the writer’s feelings rather than other content. A few were *filter blogs*, providing pointers to other content of interest and perhaps deriving from the earlier Web genre of *hotlists* or, they suggest, from the off-line antecedent of *letters to the editor*. Other types of blogs identified include *community*, *travel*, *memory*, and *communications blogs*, though these were rare in their sample.

Other authors have analyzed particular genres of documents commonly appearing on the Internet, such as the *personal home pages* mentioned above,^[59–61,66] *Web resumes*,^[67] *Internet advertising* (“netvertising”),^[68] and *online encyclopedias*.^[69] Howard^[70] went as far as to claim the existence of a “Web vernacular”, a particular form of Web page that was expected and so copied by commercial developers.

Still others have examined non-textual documents, such as *audio loops* (short sound sample),^[71] *multimedia*,^[72] and *databases*,^[73] as well as mixed media such as *PowerPoint presentations*.^[74] Exploration of genres of digital documents therefore blends at some point into the study of non-textual genres. The discussion above can be extended to such documents. For example, we can see the recreation of genres of music (e.g., *pop song* or *concerto*), even as the medium shifts from LP to CD to MP3, as well as adaptation of the genres of *television shows* to take advantage of the increased functionality (and decreased screen size) as they move from broadcast TV to Web distribution.

Genre Classification

While we do not have a list of all of the genres on the Internet (nor is it clear that such a thing is even possible), there is a substantial body of work categorizing genre in printed documents and some work studying them on the

Internet. Many attempts to develop a categorization of genres have been top-down, that is, they analyzed a set of documents based on theoretical principles or according to a priori classifications. A key difference in these efforts is the number of genre categories distinguished. Many studies of Web pages have used fewer broader categories: for example, zu Eissen and Stein^[75] used only eight genres (*help*; *article*; *discussion*; *shop*; *portrayal, non-private*; *portrayal, private*; *link collection*; and *download*). At the other extreme, Görlach^[46] offered a catalog of some 2000 genre (or text type) terms, which is intended to be an exhaustive list of the terms used in English. Somewhere in between, Lee^[11] categorized documents in the British National Corpus (BNC) into 70 genres or subgenres (with some document assigned more than one genre). However, he notes that the genre terms used were “meant to provide starting points, not a definitive taxonomy,” for example, grouping *textbooks* and *journal articles* as *academic texts* that can be further distinguished by medium.

If the classification includes more than a handful of terms, it is useful to group together similar terms and necessary to deal with terms of different levels of generality.^[11] For example, *social science papers* might be grouped with *computer science implementation papers*, *biology research papers*, and so on as examples of *academic papers*. These genres share some similarities, such as a title, abstract, and bibliography, but differ in other particulars, such as the expected section headings, types of arguments or evidence. Many organized lists of genres are structured as single hierarchies. Fig. 1 shows a small section of the hierarchy of genres of Web documents identified by Crowston and Williams.^[58] *Advertisements* and *announcements* are both examples of *declaratory document* genres; *classified advertisements* are a special kind of *advertisement*, and so on. Similarly, *social science papers*, *computer science papers*, and *biology papers* might be seen as examples of a more general genre of *research papers*, which are in turn examples of *papers* or *articles*.

An advantage of a hierarchy is that it avoids the need to predetermine the level of detail needed in the classification. Depending on the circumstances, we can consider genres at any of these different levels and different levels

might be more or less useful for different purposes. Of course, there is no guarantee that convenient and well-known terms will exist for all levels of the hierarchy. A second criticism of traditional hierarchies is that they rely on a single organizing principle, which may not be useful or appropriate for all cases. Harrell and Linkugel^[5] note that there are multiple bases on which such a classification could be constructed. To overcome this problem, Kwaśnik and Crowston^[76] suggested using the faceted-analysis approach, following the example of previous genre-identification studies such as Päivrinta,^[77] Tyrväinen and Päivrinta,^[78] and Karjalainen et al.^[79] who looked at the management of enterprise documents, and Kessler, Nunberg, and Schuetze^[80] who sought to identify a limited set of facets for communicative purposes. Crowston and Williams^[58] based their classification of genres on the *Art and Architecture Thesaurus*,^[81] which is also a faceted classification overall.

The previously discussed classification schemes can be described as top-down or *a priori*. Though this approach is quite common in conventional settings, given the communal nature of genres, a top-down approach to classification seems problematic. As genres are socially constructed, different social groups using documents with similar structural features may think about them and describe them differently (i.e., as different genres, though perhaps similar text types^[11]). While many genres may be widely shared, even more will be local to particular groups. Documents may be of genres that are not necessarily vetted by traditional schemes, particularly documents that come out of domain-specific work. Furthermore, while genres have always been conceptualized as dynamic, Dillon and Gushrowski^[61] point out that genres are no longer necessarily “slow-forming, often emerging only over generations of production and consumption...” Thus, a static typology of genre or document forms may not be sufficient to describe the emerging and dynamic genres in use on the Internet. It seems important instead to capture users’ own language and understanding of genres.

Some researchers have attempted to identify genres bottom-up through user studies. Dewe, Karlgren, and Bretan^[82] asked users to provide lists of genres found on the Web and received 67 responses. They noted though

<declaratory document genres>	
Advertisements	
Classified advertisements	Short paid announcements appearing in a periodical sorted according to the good or service being offered or requested
Announcements	Printed or published statements or notices that inform the reader of an event or other news
Custom 404 page	A Web page announcing that the requested Web page could not be found on the server
News bulletins	
Press releases	Official or authoritative statements giving information for publication in newspapers or periodicals

Fig. 1 A section of a hierarchy of document genres.

Source: Crowston, and Williams.[[104]]

that users tended to conflate genre and topic. Nilan, Pomerantz, and Paling^[83] surveyed 242 Web users in person and via the Web about their purpose in searching the Web, the genre of document expected and the actual document found, and collected 1335 example pages; genres could be assigned for 1076, giving a total of 116 genres. They then grouped the genres given, first following the plan of the *Art and Architecture Thesaurus* and second based bottom-up on the user responses. The second classification was much broader and shallower than the first, and some genres were classified in multiple locations, suggesting that there may be difference between genres in use and formal structured knowledge. Freund, Clarke, and Toms^[84] developed a list of 16 genres based on interviews with users and analysis of document repositories in a particular organization. They found that the 16 genres covered about 75% of documents randomly sampled from the repositories.

APPLICATIONS OF GENRE IN INFORMATION SCIENCE

In this final section, we discuss how ideas about genre might be applied to system design. Researchers have addressed a variety of information systems design questions, such as the use of genre to design electronic meeting systems^[38] or to guide assembly of output documents from a content management system, for example, creating training documents by reusing content from operations manuals.^[79,85] We will focus on one particular question likely to be of interest and importance to information scientists, namely how genre metadata might be used to improve information access on the Internet.

A significant problem in information access is that topic alone is not enough to define an information problem. Different users may require different solutions for seemingly similar topics because the situation (or context) of the user determines not only what topics are requested and what strategies are invoked in searching and evaluating output, but also what types of resources are considered relevant and useful. For example, “methods for learning mathematics” (a topic) will be construed differently by a student, by a parent, and by a classroom teacher because of their different information-use situations. Indeed, even the same user may require different information at different times.

Although we know that it is important to understand the situation of the user, the actual representation of situations and then their implementation in a system remains a difficult problem. Our efforts to create user profiles, universal situation grammars, and so on suffer from limitations of scope to specific domains and lack of extensibility and flexibility. However, in a study using Text Retrieval Conference data, Karlgren^[86] found significant differences in style between documents judged relevant and not relevant,

suggesting that non-topical metadata can be helpful. In particular, inclusion of genre information as non-topical characteristics of the documents might be useful as a signal to their purpose and so fit the user information need. For example, a university professor looking for information about computer database systems for the class that she teaches would most likely be interested in documents of educational genres (e.g., *syllabi*, *assignments*, *class notes*). On the other hand, when working on a research paper in the database area, the same professor would more likely appreciate scholarly work (e.g., *research papers*, *annotated biographies*, *calls for papers*). The relevant documents for these two searches would be quite different, even though the topic and query keywords might be nearly the same.

Explicit identification of genre seems likely to be particularly important for large digital collections (the Web being the largest) because—unlike earlier collections of documents comprising a limited set of genres (e.g., a document database containing primarily *journal articles*)—these collections contain documents addressing a diversity of discourse communities with a diversity of genres (e.g., *journal articles* but also *magazine articles*, *hot lists*, *memos*, *home pages*, *class syllabi*, etc.). A user searching such a diverse document collection by topic will likely receive some documents of relevant genres along with many documents of irrelevant genres—a low precision result—even if all retrieved documents conform to search specifications regarding the topical content of the document. This analysis suggests that one way to exploit genre information is to create specialized search engines that retrieve only documents of a particular genre. This approach has already been followed by several systems, such as Indeed for *job listings*, CiteSeer and Google Scholar for *academic articles* and various Google specialized searches for *blogs*, *books*, *business addresses*, *news articles*, *patents*, *product sales pages*, and *source code* (but excluding those specialized by media, e.g., searches for images or video).

A second way to use genre information is to enrich queries with information about expected genres of the results, for example, as a form of relevance feedback.^[86,87] Because most genres are characterized by both form and purpose, identifying the genre of a document provides information as to the document’s purpose and its fit to the user’s situation, which can be difficult to assess otherwise. When medical information is sought, identical keywords might retrieve a *newsletter*, a *personal home page*, a *journal article*, or a hospital’s *patient-information site*. A person searching for one of these genres is unlikely to be satisfied by the others.

Knowledge of the form of genres can also help in the process of matching documents to queries. For example, an *FAQ* document is divided into question and answer pairs (indeed, documents of many genres have a form with repeated subpieces). Requiring search terms to be found in

the same question-answer pair (or subpiece) may reduce spurious matches or false drops.

Once a search is completed, document genre may be useful to improve the accuracy of relevance judgments made to rank order search results. It has been noted that some genres are less likely to be relevant for the majority of search tasks. This implies that certain Web pages could be promoted or demoted in the ranked results if their genre were known. For example, it has been claimed that most searchers are not interested in retrieving *personal home pages*,^[88] so the latter could be moved down the results list by request. Bretan^[89] suggested using genre to group search results while Freund, Clarke, and Toms^[84] suggest filtering results.

Finally, a one-size-fits-all approach to summarizing or evaluating Web documents is likely to misrepresent many documents when confronted with diverse genres. For example, a *newspaper article* can often be summarized by the first few paragraphs of the document, but such an approach will not work for a *home page* or *FAQ*.^[90] Rehm^[91] analyzed the necessary components for a document to be an *academic home page* as a prelude to extracting information for further processing.

Automatic Identification of Document Genre

For genre to be useful in large-scale systems, techniques will be needed to automatically assign genre to large collections of documents. Researchers have tried numerous approaches to automatic genre identification; a sampling of studies is shown in Table 1. This work has used statistical (e.g., regression or discriminant analysis) or machine learning techniques (e.g., decision trees or support vector machines) to classify documents into genres based on features in the documents (Sebastiani^[92] has reviewed these techniques). Comparing the algorithm's assignment to the known genre measures the success of the classification. Table 1 presents accuracy, though the some authors compute both precision and recall. For example, Freund, Clarke, and Toms^[84] suggest that for filtering, higher recall might be preferred even at the cost of lower precision, to ensure that all documents of a given genre are presented to the user.

Document features that have been suggested for use in genre recognition include counts of specific words or of closed-class words (e.g., days of the week), counts and ratios of parts of speech, word and sentence length, layout features,^[93] punctuation,^[94] URLs, and HTML tags,^[95] and even the level of spelling and typing errors in the document.^[96] There has been a trend toward the use of larger and more comprehensive feature sets, from which the machine learning techniques can pick useful subsets. Which features are useful and necessary is still a topic for research. For example, Dewdney et al.^[93] suggested that presentation features alone were sufficient to recognize genre, while Ferizis and Bailey^[97] found that POS tagging

was not needed for genre recognition; since it is computationally expensive, avoiding these features may be desirable. Dong et al.^[98] found that more features increased recall but decreased precision, and that including more types of features improved both.

For statistical analysis or machine learning to be successful requires a large set of categorized documents to use as a training set. Creating such corpuses is time-consuming, so early studies used preexisting ones, such as the Brown corpus, which includes 500 samples (802 documents) in 15 text categories (*press reportage; press editorial; press reviews; religion; skill and hobbies; belles lettres; miscellaneous U.S. government and house organs; learned; fiction general; mystery and detective fiction; science fiction; romance and love story; and humor*). However, this corpus is not very suitable for the purpose as the average of 30 samples per genre is small for training and the categories mix topics and genres. More recent studies have created corpuses that are more focused and often larger (as large as 5–10 thousand pages with hundreds of examples of each genre). A concern here is the diversity of the documents included. Techniques applied to a corpus that includes only particular genres will yield more precise results than would be obtained with a more diverse sample.

Another key issue is number of genres to be recognized. Most studies have used small number of categories (from 4 to a maximum of 32, with a median of 10 in the studies in Table 1), which is small compared to the hundreds found in the user studies and general Web surveys reviewed above. Experimenters have examined fewer genres because increasing the number to be detected reduces precision and demands a larger corpus for training. But as Boese^[99] noted, definitions of broader categories have been “softer” to include more documents and so very broad categories may be less useful to users or for the information access systems discussed above. Another concern is that the design of classification interacts with the features chosen. Grouping together documents with similar purposes but dissimilar structural features (i.e., genres as opposed to text types) may be useful for users, but creates problems for automatic classification. With a faceted classification, different techniques could be used to recognize individual facets.^[100] Researchers have experimented with recognizing speech acts in e-mail,^[101] a document's degree of expertise, detail, and subjectivity,^[102] or positive and negative tone in reviews.^[103]

CONCLUSIONS AND OUTLOOK

The research reviewed in this entry suggests that genre provides a useful lens for examining Internet documents. First, knowing the set of genres in use by a target audience can help ensure that information presented is easily understood and used. As well, there seems to be good potential

Table 1 Studies of automated classification of documents by genre.

Study	Techniques	Features	Corpus	Typology	Results
Karlgren and Cutting ^[105]	Discriminant analysis	20 linguistic features, such as adverb count, character count, first person pronoun count, type/token ratio	Brown corpus	Brown corpus categories	52% accuracy overall; grouping all fiction together improved accuracy to 65%
Kessler, Numborg, and Schütze ^[80]	Logistic regression and neural nets	55 features including structural, lexical, character-level, and derivative cues	Brown corpus	Three part classification of 6 genres: reportage; editorial; scitech; legal; nonfiction; and fiction; plus “brow” (popular, middle, upper-middle, and high) and narrative (yes or no)	“Good results” for reportage and fiction but not for other genres. Only small difference between using surface and structural cues
Dewe et al. ^[82]	Classification rules	40 features including lexical, textual, and genre specific features	Own corpus of 1358 Web pages	11 genres: informal/private; public/commercial; searchable indexes; journalistic material; reports; other running text; FAQs; link collections; asynchronous multiparty correspondence; and error messages	90% accuracy on first split; 66–75% on remaining decisions
Wolters and Kirsten ^[106]	k-nearest neighbor classification, Relational Instance-Based Learning (RIBL); learning vector quantization; Instance Based Learning (IBL)	100, 500, or 1000 lemma features and 54 part of speech tags	Limas corpus, a collection of 500 German documents modelled on the Brown corpus	33 categories taken from the Deutsche Bibliographie (not all genres); but experiments run with fewer: academic texts from humanities and from science and technology; press texts; fiction; politics; law; and economy	75–100% precision in assignment, but each genre done is separately that the corpus provided too little material for training
Stamatatos et al. ^[94]	Regression and discriminant analysis suggest that regression works better than other techniques with a small number of training instances	22 features: token-level measures (e.g., word counts) and outputs from NLP processing (e.g., number of noun phrases detected, average length of a noun phrase)	Own corpus of 250 modern Greek documents, 25 of each genre	10 genres: press editorial; press reportage; official documents; literature; recipes; curricula vitae; interviews; planned speeches; and broadcast news, scripted	82% accuracy overall. Press editorial and press reportage often confused
Dewdney et al. ^[93]	Support Vector Machine (SVM), decision tree and naïve Bayes	323 word features and 89 presentation features: closed-class words, parts of speech, word and sentence length, punctuation, layout features	CMU corpus of 9750 documents	7 genres: advertisement; bulletin board; frequently asked questions; message board; radio news; Reuters newswire; television news	89% accuracy. Presentation features alone were sufficient to classify genre
Lim et al. ^[95]	Tilburg Memory Based Learner (TiMBL)	329 features in five sets: URL, HTML tags, token information, lexical information, and structural information	Own corpus of 1224 Web pages	16 genres: Dewe et al.’s ^[82] taxonomy, plus product specifications and image collections, and splitting public and commercial homepages in two, and reports into research reports, official materials and informative materials	74% accuracy in assignment; improved slightly with optimal subset of features. Could not reliably determine genre for input pages and other
Bisant ^[107]	Neural network with hidden layer, decision trees, SVM	89 features including part of speech and characters. Analysis shows 25 are not useful	Own corpus of 5000 e-mails and Web pages	10 genres: advertisement, business correspondence, data entry forms, e-mail administration, e-zine, friend correspondence, Internet chat, news, notices, and technical data	86% overall accuracy using neural nets with considerable variation. Decision trees are 79% accurate. Notices confused with news

(Continued)

Table 1 Studies of automated classification of documents by genre. (*Continued*)

Study	Techniques	Features	Corpus	Typology	Results
Boese ^[99]	Bayes Net, decision trees, logit boost, bagging	Considered 1600 features: style, form, content. Narrowed to a set of 78	Own corpus of 343 Web pages	Developed classification of 115 genres but used 10 for experiments: abstract; call for papers; FAQ; how-to; hub/sitemap; job description; resume/CV; statistics; syllabus; and technical paper	91% accuracy using logit boost and 78 features
Freund et al. ^[84]	SVM light	"Bag of words," but no structural features	Own corpus of 800 documents (about 50 per genre) drawn from repositories in a single organization	16 genres (manuals; presentations; product documents; technotes, tips; tutorials and labs; white papers; best practices; design patterns; discussions/forums; cookbooks and guides; engagement summaries; problem reports; technical articles) developed within a specific organization	81–97% recall, but lower precision
Stubbe et al. ^[96]	Decision trees	Hand selected sets of genre-specific features: form, vocabulary and parts of speech, complex patterns, level of typing errors	Own corpus of 1280 Web pages, 40 of each genre	32 genres in 8 broad classes: journalism, literature, information, documentation, directory, communication, nothing	78% accuracy at first level; 72% at second level with considerable variation
Dong et al. ^[98]	Naïve Bayesian	5, 20, or 100 features from form, content, and functionality	Corpus of 1280 Web pages; 170 of 4 genres (3 from Santini, M. ^[48]) plus 600 random pages	genres: FAQ; news; e-shopping; personal home pages	86–92% accuracy (precision). Precision improved by fewer features, but recall by more. More types of features improved both

to incorporate genre metadata in information access systems. However, to realize these benefits, more research is needed. First, we do not as yet have a fully articulated set of data that reveals what genres various target groups recognize nor for what tasks they find documents of specific genres useful. Second, while genre recognition has improved, it is still limited in the number of genres that can be detected reliably. These two research agendas interact, as better knowledge of the genres in use will inform our attempts to recognize and use them in future Internet systems.

Internet Search Tools: History to 2000

Dale J. Vidmar

Connie J. Anderson-Cahoon

Southern Oregon University Library, Ashland, Oregon, U.S.A.

Abstract

The early history of Internet search systems was quite diverse, and went through several stages before settling into the more mature recent environment of a few major search engines. The authors note: "From the early beginnings of Telnet, File Transfer Protocol (FTP), Archie, Veronica, and Gopher to the current iterations of Web search engines and search directories that use graphical interfaces, spiders, worms, robots, complex algorithms, proprietary information, competing interfaces, and advertising, access to the vast store of materials that is the Internet has depended upon search tools."

INTRODUCTION

Finding information on the Internet and the World Wide Web (WWW) has always been somewhat like trying to find a needle in a haystack. An added dimension to the haystack metaphor is that the Internet environment is a dynamic collection of information. Changes occur almost every second. New pages are added. Old pages are deleted or altered. From the very beginning of the World Wide Web (WWW), search tools were needed to create order and provide an interface that allowed users to retrieve current documents while at the same time deleting inactive sites. Search databases and indexes could not be static; neither could the interface that served as the public relations instrument for the product. The tools of Internet searching emerged from the simple and modest beginnings of research and graduate school projects to the highly competitive and highly secretive proprietary corporate environment. As search tools evolved, they changed not only how people find information, but also how they viewed the world of the twenty-first century.

The Internet grew out of a need to connect computers at one location to computers at other locations, thus creating a globalization of shared resources. The early iterations of shared data were basic but grew rapidly as more and more computers became connected. Connectivity led to an information base that multiplied and evolved exponentially. This information base ultimately became unwieldy, and some of the early Internet pioneers began to see the necessity for both an organizational scheme and a method for accessing what was available. Each new tool provided more order, and in general an improved searching mechanism. From the early beginnings of Telnet, File Transfer Protocol (FTP), Archie, Veronica, and Gopher to the current iterations of Web search engines and search directories that use graphical interfaces, spiders, worms, robots, complex algorithms, proprietary information,

competing interfaces, and advertising, access to the vast store of materials that is the Internet has depended upon search tools.

THE BEGINNINGS

What we now know as the Internet had its origins in the early 1960s by several visionary thinkers who understood the value of having computers linked to one another and being able to share information. Most applications were in the scientific and military fields at that time. Early developers included J. C. R. Licklider from MIT, who proposed a global network of computers in 1962. Licklider moved to the Defense Advanced Research Projects Agency (DARPA) and became the head of the project in late 1962. Leonard Kleinrock from UCLA developed the theory of packet switching that later became the basis for Internet connections. An MIT professor, Lawrence Roberts, connected two computers via telephone lines in 1965. Roberts became part of DARPA in 1966 and developed the plan for ARPANET. In 1969, the U.S. Department of Defense changed the name of DARPA to the Advanced Research Projects Agency (ARPA).

The purpose of ARPA was to develop and maintain automated communication methods that would operate in an emergency. As a result, ARPANET, a distributed communications network capable of communicating with multiple computer platforms, was born in 1969. Ultimately, these multiplatform and multichannel methods became known as the transmission control protocol and Internet protocol (TCP/IP), which for the most part defines the Internet as it is now configured today. Data are encoded and transmitted between computers via the common format TCP/IP provides. TCP/IP protocol was first proposed by Bob Kahn at BBN Technologies, a division of GTE, and further developed by Kahn and Vint Cerf at Stanford.

The National Science Foundations (NSF) extended its network in the 1980s to increase international educational and research opportunities. This network used NSF computers for data storage, file transfer, and E-mail. NSFnet evolved into what is now known as the Internet. It incorporated the TCP/IP format. As the Internet grew, there became an increasing need for better tools to access and organize information. Using FTP information could be shared between computers. File transfer protocol enables a user to obtain files of text, executable programs, graphics, movies, sound files, and other information, but early restrictions of FTP sites allowed only short names with little description about content. Files were often named README, INDEX, NOTICE, ABOUT, and other variations. These file names were typically capitalized, so they appeared in a more prominent position in a list of entries. There were thousands of FTP sites across the world, but each site was a collection of files that were not searchable. A user would have to visit each FTP site and browse through the files to hopefully discover relevant information. Archie, Veronica, Gopher, Wide Area Information System (WAIS), and others were the early search tools of the Internet—the first attempts to provide more order and searchability. Although these early tools are still accessible today, they were developed prior to Web browsers and have generally been replaced by more popular Web search tools.

Archie

In 1990 Alan Emtage, Peter Deutsch, Bill Heelan, and others created the oldest search engine at McGill University in Montreal. At the time, there was no World Wide Web, and files were scattered over a vast network. These files were stored and retrieved via FTP. The transfer of publicly available information has been one of the most widespread uses of the file transfer capability on the Internet. Institutions and organizations throughout the world provide openly accessible file transfer sites with information that anyone can obtain. Archie short for “archives,” was a manually indexed system for exchanging these types of files, particularly the very popular anonymous FTP sites, which were repositories of files that anyone could access. Archie was a search tool for finding things in FTP space based on keywords.

Prior to Archie, a system administrator set files up on a computer called an FTP server. Those files could then be retrieved by someone else by connecting to the files via an FTP client following specifications set forth in FTP protocol. These files were generally shared by sending an E-mail alerting others of the location of the files or by posting a message to a listserv or discussion forum. Archie used a script-based data gatherer to retrieve listings of anonymous FTP files. It then made these files accessible by indexing them. The result was a method of organizing files into accessible listings, but Archie servers generally contained only a small portion of available information.

Gopher

Gopher was developed at the University of Minnesota in 1991. It was named Gopher after the University’s mascot—the Golden Gopher—suggesting a user “go for” information. Gopher was designed to be an easy, menu-driven way of finding online information. Mark MacCahill, project leader, described the program as “the first Internet application that my mom and dad could use.” Gopher did not require any knowledge of computer architecture or UNIX to use. Gopher was like FTP except that it retrieved plain-text documents rather than files, having no images or hypertext. In a gopher system, typing or clicking on a number that represented the document on a menu accessed a hierarchically structured list of documents. Menu entries were more descriptive than FTP sites. Gopher searched through files and resources in a variety of formats—text, Telnet sites, WAIS databases, and a wide range of other data—in order to find online information.

Gopher was popular for several years, especially at universities, because it provided a way to share text files from all over the world. Gopher was a step toward the WWW hypertext transfer protocol (HTTP). Ultimately with the advent of hypertext links, hypertext markup language (HTML), and a graphical browser—Mosaic and later Netscape—the Web quickly transcended gopher. Most gopher text files were eventually transferred to Web documents, but many original file structures still exist on university servers. A gopher client program is needed to run gopher. Public gopher sites are available via Telnet without the client program, however. To explore an example of gopher information hierarchy, go to the gopher menu at the University of Minnesota at: <gopher://gopher.tc.umn.edu:70/11/Other%20Gopher%20and%20Information%20Serves>. The major limitation of Gopher was burrowing through all the sites to find needed information. Like FTP files, Gopher needed keyword searching to access information more effectively.

Veronica

The usability of Gopher was further enhanced by the development of Veronica at the University of Nevada at Reno. Fred Barrie did most of the programming. Veronica stands for very easy rodent-oriented netwide index to computerized archives. Rodent-oriented refers to the way in which Veronica works with the Internet’s gopher systems. Veronica searched public-access gopher menus using keywords in much the same way as Archie searched FTP sites. Veronica retrieved a list of entries from various gopher sites throughout the world and enabled a user to browse entries from a newly created single menu composed of entries related to the search query. Like Archie, however, the major drawback of Veronica was that it searched only file names, not the contents of files.

Jughead

Jughead, an acronym for Jonzy's universal gopher hierarchy excavation and display, is another gopher search service that works in a way similar to Veronica. Rhett "Jonzy" Jones developed Jughead in 1993 at the University of Utah. Jughead allowed keyword searching throughout all levels of a gopher menu rather than moving from one menu level to another. Jughead did little to improve upon Veronica, which lends credence to the belief that it was invented primarily to round out the comic-strip characters rather than providing much new in terms of searching software. Jughead did, however, allow Boolean "and, or, not" searching and recognized truncations using an asterisk after the root of a term.

WAIS

The WAIS was developed by Brewster Kahle at Thinking Machines Corporation of Cambridge, Massachusetts, in collaboration with Apple Computer, Dow Jones, and KPMG Peat Marwick. It was developed at about the same time as Archie, in the early 1990s. WAIS was a system for organizing information into databases that could be searched using commands known as natural query language. The WAIS software performed keyword searches of databases and refined searches based on relevancy as determined by an algorithm—a series of steps or formulas designed to retrieve information by indexing data based on "weighting." The intent was to give more relevant documents a higher score or weight based on the search query. The WAIS search engine processed a search by retrieving a relevance-ranked list of documents. Each document was given a score from 1 to 1000 based on how well it matched the search expression. A search could be executed in the form of a question, through natural language, or by use of specified fields. To use WAIS effectively to find information, files and data in every site needed to be indexed, which was not the case. After the introduction of Mosaic and Netscape, WAIS was eventually used as a back end search engine for HTTP servers to find everything from relative hyperlinks to image references.

Search Tools: The World Wide Web and the Next Generation

When Tim Berners-Lee developed HTTP, the basis for graphical interface to the Internet, the WWW was born. The WWW changed the face of the Internet so much that the words Web and Internet became almost synonymous. HTML, the standard coding language for viewing and linking documents, allowed users to move from document to document by simply clicking a link. HTML also provided access to graphical representations and images. Telnet, FTP, Archie, and Gopher required knowledge of how to navigate nonintuitive interfaces.

A variety of databases that could be described as search tools were developed for the WWW. When the Web was in its infancy, Lynx was the browser of the day. Lynx was a text-based interface in which a user entered a specific address of a known page and began to "surf" through information by following links. It was possible at the time to navigate through the available information because the Web was relatively small. In 1992, the number of hosts or servers storing sites had just grown to over 1,000,000; in January 2000, that figure had grown to more than 72,000,000. With the introduction of Mosaic early in 1993 and its offshoot Netscape—graphical user interfaces or Web browsers—the Internet became more accessible, and individuals with personal computers took notice.

While Gopher was an improvement over the capabilities of Archie, it was essentially a table of contents that provided access to downloadable files. Veronica and Jughead advanced that technology, making gopher files searchable, but the Web offered users the ability to display text, graphics, illustrations, sound, video, voice, and other forms of information. Search tools depended on interfaces and the technology that created search engines, human-indexed subject directories, and other more user-friendly means of accessing information from the Internet. As search tools improved, easier, more intuitive modes of navigating the Internet and transferring information became readily available. With improved access to information, the WWW and Internet grew in staggering proportions.

Search Engine Technology: Robots, Spiders, Wanderers, Crawlers, and Indexers

Modern search engines are indexed databases of Web pages compiled by powerful programs called robots (also called bots, spiders, wanderers, or crawlers). Robots are a key component in Web search technology. They can perform a variety of tasks very quickly and efficiently, such as indexing, statistical analysis, maintenance, mirroring, and discovering new resources throughout the Internet. In addition, robots can be programmed to do one or several of these operations. In the early days of robots, bandwidth was at a premium and the seemingly tireless bots created a drain on server loads. During the minutes after the O. J. Simpson verdict, the CNN site was so overloaded it was virtually inaccessible.

Robots are basically software programs that work by retrieving documents using HTTP to request a specific Uniform Resource Locator (URL)—essentially the "address" to a Web page. Robots do not actually go anywhere. More accurately, they establish a connection with another server and compile the information about specific URLs or Web documents. The Internet search engine that uses a robot is essentially a program that searches documents for specified keywords and returns a list of the documents in which the keywords were found. A typical

search engine works by sending out a request through a robot program that retrieves as many documents as possible. The robot moves through the Web surveying pages and indexing most of the words on publicly available sites. Most robots begin by searching an active page with a variety of links, following the links on the page to other pages and other links.

Another program, called an indexer, then reads these documents and creates an index based on the words contained in each document. By systematically exploring all links on a starter page and following those links, the spider tracks a large number of pages in the database and creates listings based on keywords. Every search engine uses different information from the Web sites to create its database. For example, some will use just the title and the first 20 words of the Web page. Others may go further, examining links and headers on a page. Consequently, the databases of search tools contain a variety of differing information, sometimes collected from the same sites. The spider will later return to sites to check for changes, adding and deleting content as necessary. A critical measure of a search engine is how often it refreshes its database to remove dead links and add revised pages.

When a query is sent to a search engine, the engine scans the database and matches keywords and phrases from the query with those in texts of collected Web sites. Every search engine has its own proprietary algorithm that ideally retrieves meaningful and relevant results for specific queries or searches. It is precisely these distinctly different and secretive programs for displaying a retrieval set that offer more variations and options to finding information on the Internet.

The Wanderer

The Wanderer, the first program to automatically traverse the Web, was created by Mathew Gray and is described by some as “the mother of all search engines.” The Wanderer was the first autonomous robot program designed to search the Internet for Web pages to track the growth of the Web. At first, the Wanderer only counted Web servers, but before long it started capturing URLs. The resulting database of URLs was dubbed Wandex. The Wanderer was contentious when it was first introduced because the early version of the software created a noticeable slowness across the entire network. The Wanderer’s bot program often accessed the same pages hundreds of times during the same day. The Web robot was a significant innovation, however, because it automatically combed through Web documents at a speed fast enough to maintain a current database that included new pages, updates, and revisions as well as renamed and relocated documents. While the Wanderer used a single bot program, search tools eventually began using multiple bots or spiders that perform different tasks. This was the beginning of the automated Web searcher.

ALIWEB

ALIWEB, created in October 1993 by Martijn Koster, was an early project designed to index the contents of Web servers. The name ALIWEB is derived from the name Archie-like indexing of the Web. It is unique because it is the hypertext equivalent of Archie. Unlike the Wanderer, ALIWEB does not have a Web-searching robot. Webmasters posted information for each page in order to have them included in the database. While this allowed the creators of Web pages to describe and index their own sites, it also required that they maintain a special ALIWEB file on their server. ALIWEB then used a robot to search for these special files, compiling them into an index. The disadvantage of this system is the most Web page developers either did not bother or did not understand how to create the special indexing file required, and therefore very few pages were submitted to the Internet utility. The major difference between ALIWEB and other search engines is that the typically proprietary information about how the robot worked was posted on the Internet by Koster. This allowed other programmers to modify future robots to perform additional tasks, such as finding additional Web pages and gathering information from the text of those pages. It even became possible for individual users to configure their own spiders to find sites about specific topics and automatically retrieve the information from those sites.

THE UNIVERSITY CONNECTION

Jumpstation

Many Internet search tools had their origins at the graduate schools of various major universities. In 1993, after Mathew Gray’s Wanderer unleashed the first bot program, three search engines powered by “robots” made their debut. Jumpstation was a weekend project created by Jonathan Fletcher at the University of Stirling in Scotland. Jumpstation gathered information about the title and header from Web pages, matching keywords in a linear fashion as it went. As the Web grew, the system slowed gradually before coming to a halt.

World Wide Web Worm

The WWW worm—started by Oliver McBryan at the University of Colorado—indexed only titles and URLs that it visited. The worm was first publicly available in February 1994. By following the hypertext links on Web sites, the worm took advantage of indexing sites that were “worthy” of a link by another site—an early system of referral using linking structures. On the downside, the worm also relied on the authors of Web pages for

descriptive titles and other information about a site. At the time, few authors were sophisticated enough to use metatags and other more current Web designs that provided titles or descriptions. Consequently, Web sites with little or no descriptive information could not be retrieved.

The Repository-Based Software Engineering (RBSE) Spider

The repository-based software engineering (RBSE) spider was developed and operated as part of the NASA-funded repository based software engineering program at the Research Institute for Computing and Information Systems, University of Houston, Clear Lake, by David Eichman. The search tool employed a robot that could go beyond the title and URL to index the text within Web pages. RSBE used two robots—one robot for finding and compiling URLs and a second for retrieving and indexing documents based on actual content. In addition, RBSE improved searching by implementing a primitive ranking system based on relevance. The search results for its predecessors, Jumpstation and the WWW worm, were posted in the order they were found, so often the results were often irrelevant.

EINet Galaxy

Another early search tool to emerge during this time was the Enterprise Integration Network—EINet Galaxy. EINet was the first Web search directory that could be browsed or searched. Launched in January of 1994, EINet Galaxy combined WWW and WAIS technologies, compiling information into a hierarchical list of sites organized by subject categories. The original prototype was associated with the DARPA-funded Manufacturing Automation and Design Engineering (MADE) program, intended to explore technologies for providing large-scale directory services in support of electronic commerce.

EINet's directory was created and maintained by humans, as opposed to the robots used by search engines. As one of the original "search directories," EINet originated categories that are fairly common in more modern search tools. The original Galaxy index arranged information under nine topics: arts and humanities, business administration and management, engineering and technology, general and interdisciplinary information, leisure and recreation, science, government, social sciences, and community. Each URL that was added to the site was submitted to EINet, then reviewed by editors specializing in subject areas. The search directory generally retrieved higher-quality Web sites that were more relevant, but also had a database of far fewer sites because they were cataloged by hand. EINet was purchased in 1998 by GoTo.com and merged with Fox/News Corporation in May 1999.

Yahoo!

In April of 1994, two electrical engineering Ph.D. candidates, David Filo and Jerry Yang from Stanford University, started a guide of personal interest Web pages that became quite popular. The guide began as a humble Web site named "Jerry's Guide to the World Wide Web." It was a student project that was a small collection of their favorite Web pages. When the collection began to become unwieldy, Filo and Yang broke the links into categories, then later subcategories. There was no business plan or calculated design to become a major publicly traded corporation. Filo and Yang were trying to create something that would make finding information on what was at the time a very small WWW. The guide became popular by word of mouth and E-mails to friends who then told others. As it continued to grow, Filo and Yang changed the name to Yahoo! which stood for "yet another hierarchical officious oracle." They chose the name as a reference to themselves as a couple of "yahoos," a term originating from Jonathan Swift's *Gulliver's Travels* that referred to a boorish, foolish class of people.

It was Filo and Yang's "foolishness" that led to one of the premier search services on the Internet. The database of categorized links first resided on Yang's computer, "akebono," a hierarchically organized list of 14 broad categories covering subjects such as business and economy, computers and the Internet, entertainment, and health. By following the hierarchy, a searcher could click down the subject areas from the main subject areas to thousands of deliberately chosen Web sites. As Yahoo! grew, a simple search engine was added, which was stored on Filo's computer, "konishiki." Filo and Yang developed customized software that allowed them to efficiently locate, identify, and edit documents stored on the Internet.

All of Yahoo's entries are categorized using human editors, so it is not really classified as a search engine, but as a searchable directory. Yahoo! discovers new Web pages primarily by submission by authors or others who submit a new URL for review. What sets Yahoo! apart from other search tools is its browsable hypertext classification structure combined with an editorial review of Web sites. It was originally designed to have intuitive paths to information. Yahoo! actually created only a brief description, title, and URL for each page it displays, then links to the actual page. As such, it is not possible to search the actual text of a Web page, but the classification system by which the sites are cataloged generally leads users to higher-quality documents.

Due to its popularity, Yahoo! executed more searches than many of the other search tools of its time. As such, it was in a better position than its competitors to gather information about what people were searching and what they were interested in. Yahoo! used this information to cater to emerging trends and launch affiliate sites based on interests, trends, and geography. Gathering information

about what users search and, more important, how they executed their searches was a key to designing better search tools from the very beginning, and it continues to guide development.

WebCrawler

In early 1994, students and faculty from the department of computer science and engineering at the University of Washington gathered at an informal seminar to talk about the Internet and the WWW. WebCrawler was an idea that emerged from one of these seminars. Brian Pinkerton created a single user application that found information on the Internet as a research project. Pinkerton was then persuaded by fellow students to develop a Web interface. WebCrawler was the first full-text search tool on the Internet. Not only did it capture URLs like other robots, but WebCrawler's robots could capture information and links from the entire text of Web pages. In addition, the robots indexed pages using past results to direct future results using both new URLs and old URLs that were already a part of the WebCrawler index. Pinkerton's search tool worked on the assumption that links would have information relevant to the subject matter of the original Web document.

WebCrawler was released to the public on April 20, 1994, with a database containing about 6000 servers on the Web. As WebCrawler became more popular, it began to overload the network at the university. By October 1994, Web Crawler was receiving an average of 15,000 queries per day. Although a number of companies had tried to ease the load on the servers by investing in server equipment, by March 1995 Web Crawler was so popular that it became unusable during the day. It became obvious that the University of Washington could not financially support the project on its server without additional funding by outside advertising. Due to the potential conflict of interest that soliciting advertising revenue might cause, WebCrawler was sold to America Online (AOL) on March 29, 1995. AOL began to run the service on its own network as AOL NetSearch. Excite Inc. bought WebCrawler from AOL in November 1996, adding the service to its other search products, Excite, WebCrawler, City.net, and Magellan. About a year after WebCrawler was first introduced, Lycos, Infoseek, and Opentext emerged. These three new competitors all improved on WebCrawler's basic functionality.

Lycos

John Leavitt's LongLegs program provided the basis of Lycos. Michael Mauldin led a team from the Center for Machine Transition at Carnegie Mellon University that began development work on Lycos in May 1994. Lycos's name was based on the Latin term *Lycosidae lycosa*, the family name of a ground spider that hunts at night by

chasing down prey rather than using a web. Similarly, Lycos's spider program gathered URLs at night. When it became available for public use on August 12, 1994, Lycos had a catalog of 54,000 documents. By January of 1995, the catalog expanded to 1.5 million documents. Lycos was licensed by Microsoft for its Microsoft Network in April 1995. The partnership was one of many by Carnegie Mellon that allowed use of Lycos but retained ownership of the search tool. In June 1995, however, CMG@Ventures purchased Lycos, forming a new company, Lycos, Inc. Mauldin received a minority take in the company that began providing advertising space to the emerging corporate market on the internet. By November of 1996, Lycos had indexed over 60 million documents.

Excite

Architext was started by six Stanford graduates, Joe Kraus, Graham Spencer, Mark Van Haren, Ben Lutch, Martin Reinfried, and Ryan McIntyre, in June 1993 in a garage in Cupertino, California. The six wanted to design a software product that would help manage the vast amount of information on the WWW. The original software combined search and retrieval with automatic hyper-text linking, subject grouping, and automatic abstracting. Using statistical analysis of word relationships based on proximity and co-occurrence of terms, the team designed software that searched more sufficiently. It would not be publicly available until December of 1994. By that time, the original six members of the Architext team secured \$500,000 in venture capital money from Kleiner Perkins Caufield & Byers and Institutional Venture Partners to launch the product. Architext evolved into the Excite search tool in October of 1995. The company quickly established itself, signing exclusive distribution agreements with Microsoft Network and Netscape. The company officially changed its name to Excite, Inc., and went public with an initial offering of 2 million shares of stock at \$17 per share. By January of 1999, Excite, Inc. would have more than 700 employees worldwide.

Infoseek

Infoseek was founded by Steven Kirsh, founder of Frame Technology and Mouse Systems, and a team of high-tech industry professionals in January 1994. Infoseek's engine was based on Yahoo! and Lycos, and became available on March 26, 1995. Infoseek was a little more user friendly and had added features such as UPS tracking, news, and a directory. It searched the last four weeks of Usenet News and allowed natural language searching. Infoseek initially used a spider to index the full text of Web sites, but later added a human-organized directory. What launched Infoseek into the public market was the move it made with Netscape. Netscape first used Yahoo! as its default search engine, but in December of 1995, Infoseek paid Netscape

to have Infoseek as the default search engine when the program starts.

Infoseek also signaled the beginning of commerce-based tools by taking advantage of advertising via the Web. At that time, Infoseek appointed Robin Johnson, the former senior vice president of corporate development at Time Inc. as the new president and CEO. Johnson's background in the advertising-supported publishing industry was a perfect mix for a popular Internet search tool with approximately 5 million hits per day. Infoseek became the first search tool to support itself through third-party advertising using the cost per thousand model (CPM). The pricing model was intended to apply an advertising rate that was similar to the pricing model used by print publications. Magazines base their ad rates on the number of subscriptions or the estimated number of people who will see the ad. Infoseek created a model that was similar in that it based its price on the number of viewings that a advertising banner would receive. Infoseek charged a set price for the assurance that an advertisement would be accessed or appear 1000 times. Infoseek was also the first search tool that allowed advertisers to target their audience by linking ads to specific search terms.

Infoseek attempted to combine electronic results and the editorial recommendations for Web sites with a third component, high-quality advertising and sponsorships. Four years after it was founded, Infoseek became a predominant force in the online information management industry, publicly traded on the NASDAQ and ranking as one of the most highly trafficked single Web domains. In 1999, Infoseek Corporation combined with Walt Disney's Buena Vista Internet Group to form a new Internet company, go.com.

AltaVista

AltaVista began as an experiment to test new server hardware and searching software by Digital Equipment Corporation (DEC) that could run programs about 100 times faster than other existing computers. Using a very fast spider to gather documents, developers created a full text index of the Web and Usenet. Alta-Vista also provided software to support high-volume access to the information. The name AltaVista was a juxtaposition of "alto" from Palo Alto and "vista." Ultimately, it became "AltaVista," meaning "the view from above." As a search tool, AltaVista became publicly available in December 1995. In the summer of 1996, it replaced Open Text as Yahoo!'s official search engine, and was soon one of the top search tools, using innovative features and, more important, speed. Run on the DEC network, AltaVista could handle millions of hits per day without slowing down.

One of the innovative features was natural language searching, allowing queries using phrases as well as keyword searches. AltaVista searched with words such as *what*, *the*, *as*, and *etc.*, and retrieved results without

getting all the pages containing those words. Advanced search features included both Boolean searching and a results ranking query box that retrieved results when the words appeared in the title of a Web page. AltaVista also allowed developers of Web sites to add and delete URLs from the index, and they could search for sites that linked to a particular URL. AltaVista included a tips section to help the user make a better, more efficient search. The tips periodically changed, so each time the user accessed tips, he or she could view a new tip. Other search tools soon implemented similar "help" and "tips to searching" menus. AltaVista was also one of the first search tools to offer multilanguage searching capabilities, and later introduced the translation feature, Babelfish.

Inktomi

Inktomi began as a research project at the University of California at Berkeley by Eric Brewer, assistant professor of computer science, and Paul Gauthier, a Ph.D. candidate in computer science. The name Inktomi is derived from a Plains Indians myth about a spider that brought culture to people. Brewer and Gauthier developed highly effective technologies during their research that were used to power search tools such as HotBot and Yahoo!. Using parallel processing consisting of 100 or more standard-issue workstations lashed together, Inktomi pioneered a fast search engine service that could search over 100 million Web documents in the space of 250 milliseconds. Each of the computers processed information from the Web independently before collating the information together as a single result. After posting their search engine on the Web, Brewer and Gauthier raised about \$27 million in investment capital, including \$2 million from Intel, before becoming a publicly traded corporation in June 1998. In July 1998, Yahoo! dropped AltaVista as its search engine in favor of Inktomi.

Northern Light

Like so many other search tools with humble beginnings, Northern Light began in the basement of an old mill building in Cambridge, Massachusetts. The search tool was released for public use in August 1997. Northern Light, named after the 1851 Clipper ship with a new design and technology that made it faster than its competitors, had two major innovations that were supposed to make it better than other search tools. Northern Light organizes query results into custom search folders by subject, type, source, and language specific to that search. The folders can be used to refine or give context to a search. For example, a search for lesson plans retrieves the first 20 relevant hits. It also retrieves various folders such as class notes and assignments, mathematics, teachers and teaching, middle school, and elementary school. The folders can be used to refine or give a context to a search to help retrieve highly

relevant sites. The second innovation was the Northern Light's special collection, an online database of full-text journals, books, magazines, newswires, and reference sources that were accessible for a nominal fee of \$1.00 to \$4.00 per article.

Google

Google was developed in 1998 by two 26-year-old Stanford computer science graduate students, Sergey Brin and Larry Page. Google was named after a derivative of the word *googol*, a term coined by Milton Sirota, a nephew of American mathematician Edward Kasner. It represents the number 1 followed by a 100 zeros. The commercial Google site was launched as <http://www.google.com> in September 1999 with the help of \$25 million in funding from Sequoia Capital and Kleiner Perkins Caufield & Byers. Page and Brin pioneered the analysis of link structure as a determinant in the order of a retrieval set. Google's algorithm is based on the idea that a Web site that is linked to by others should hold a higher ranking than a site that has few referring pages. This means the quality or importance of a site is a determinant of the relevancy within a search query. Indexing a site is similar to citation indexing in that each page is assigned a value that is calculated by how many other pages refer to the page and how important the linking pages are. Even before Google was launched, it had 2 million views per day, largely by word of mouth.

METASEARCHERS

MetaSearchers, also called parallel or multiple search engines, are a group of search tools that produce a single integrated retrieval set from a query that is sent to several search engines and search directories simultaneously. A metasearch tool must contain three components: a dispatch mechanism, interface agents, and a display mechanism. Choosing search engines for a specific query is the function of the dispatch component. The interface agents then translate a query into the format required by a specific search engine or directory. When the results are retrieved from the various search tools, the display mechanism merges them. Sometimes the results are sorted or ordered either as a ranked list or as a site-by-site display. The more efficient metasearchers eliminate or reduce duplicate and inactive links.

SavvySearch

In March 1995, an ambitious student at Colorado State University (CSU), Daniel Drillinger, developed and launched SavvySearch as a public metasearch service. SavvySearch began as a project for the class "Introduction to Artificial Intelligence." The project evolved into

Dreilinger's master's project and needed four dedicated workstation computer systems at the CSU computer science department to keep the program operational 24 hours a day. The original SavvySearch service directed queries to a subselection of 19 search tools and resources. Soon the service began adding more search tools and resources, such as Usenet, and access to software and shareware. In November 1998, the search service had expanded its user-selected metasearch service to include more than 200 search tools, including specialty collections such as Scour.net and image finders from Yahoo, Lycos, and AltaVista. SavvySearch also incorporated a topical or subject-based access to other collections as well as a capacity to employ Boolean search queries for advanced searching. The ability to select and customize the metasearch process distinguished SavvySearch from other later metasearchers. Savvy Search was acquired by CNET on October 14, 1999.

Metacrawler

In the spring of 1995, Eric Selburg, a student at the University of Washington, created Metacrawler as his master's degree project. Metacrawler takes the search query that it is given and forwards it to all the big search engines. AltaVista, Excite, Infoseek, Lycos, WebCrawler, and Yahoo! MetaCrawler gained so much popularity when it was publicly released that it was mentioned in a cover article by *Forbes* magazine. Other search engine companies didn't approve of Meta Crawler because it only showed the search results of each engine and left out the advertising banner that pops up when the engine is accessed, meaning not as many ads were reaching the intended audience. MetaCrawler was changed so that the intended ads would be shown above each engine's results.

AskJeeves

AskJeeves was the creation of a venture capitalist, Garret Gruener, and a chief technology officer, David Warthen. Using natural language technology combined with a knowledge database and human editors to find Web sites that answered commonly asked questions, AskJeeves maintained a site that provided answers instead of large retrieval sets of sites. In April 1997, AskJeeves was publicly available for searching. More recently, AskJeeves has purchased Direct Hit, a technology that accesses information based on sites that are popular in similar searches. What distinguishes AskJeeves in the evolution of search tools is the concentration on human evaluation to determine the relative worth of Web sites for particular queries.

THE FUTURE

Although many search tools began in universities and graduate institutions, eventually they moved to the now

common advertiser-driven business model backed by venture capital. Within this business model, search tools provided free, unlimited access to their database while at the same time having a vested interest in maintaining a user/customer base that would increase ad revenues. Publicly owned companies selling stock and highly influenced by standard business and marketing practices have created a commercial environment in which search tools try to operate as a viable business model. Mergers and acquisitions have become common as the individual search tools group together to survive and attract more users.

Currently, the WWW is estimated at more than a billion publicly indexable sites. The “invisible” or “deep Web” contains as many as 550 billion additional sites. As of August 2000, the Open Directory Project listed 351 different search tools. That number will most likely continue to grow as more specialized search tools appear and new iterations of existing tools enhance access to information. One of the major weaknesses of the major search tools such as Yahoo!, AltaVista, Google, Northern Light, and FastSearch is that they do not index a large amount of the information available on the Web. The search tools of the next generation will require more and more integrated approaches to search technologies. Natural language, categorization, and meaning-based processing as well as information extraction, link analysis, multimedia and graphical retrieval systems, and additional value-added features will be integral to search tools designed to handle a variety of different queries. Visual, non-text-based representations of retrieval sets will allow users to graphically view relationships between documents and sites differently than the current text-based sets. Interfaces will continue to become easier to use as designs continue toward creating portals and one-stop searching to maintain a customer base that feeds the advertising stream.

More significant will be the ability for the searcher to interact with search tools to reformulate and refine queries. Metadata using the extensible markup language (XML) and resource description framework (RDF) will generate a more sophisticated and precise tagging system. The XML can provide contextual information, such as where the site was generated from, when, by whom, and other profile information. As this is further developed, searchers will have the ability to recall terms and information from previous queries. They will also be able to interact intuitively with the search interface to specify or eliminate specific kinds of contents. Queries will be customizable and have the ability to maintain criteria used in past searches. Searchers will also have the ability to add context to search terms similar to what can be done using Zapper’s Intellizap, or they can choose a context term or phrase to refine a search, such as they can in Oingo. Link structure, made popular by Google, and traffic popularity, such as that from DirectHit, will continue to drive search tools toward better accuracy and precision searching. Other search tools will develop indexes based on referral

sites from the Web community at large, like that of the Open Directory Project.

Another future dimension of Internet searching is the invisible or deep Web—the information from sites that are not typically indexed by search tools. There are as many as 550 billion sites in the deep Web as compared to little over a billion indexed sites. The information in these sites is more refined and in-depth. Currently, approximately 85% of Internet users use search tools for finding information. The basic search methodology and technology will need to evolve further in order to retrieve the vast amount of information that is beneath the surface of the Web. One thing is certain in the history of search tools—they will change and evolve, especially as the Internet continues to expand toward higher-speed access. Multimedia is growing so rapidly that search tools are becoming conduits for providing information in a variety of formats. Also, as access to the Internet expands globally and internationally, multicultural/multilingual searching will become more than a feature; it will be a necessity. Internet search tools will be essential keys to the Internet’s evolution to a truly “World” Wide Web.

Abstract

This entry presents the International research on Permanent Authentic Records in Electronic Systems (InterPARES) project, an international multidisciplinary research endeavor that, since 1998, has sought solutions to the issue of long-term preservation of the authenticity of digital records. The entry outlines the goals of the four phases of the project, its membership, methodology, principles, activities, and products, and discusses its conceptual findings—specifically, the concepts of record and of authenticity—and its methodological findings regarding archival appraisal, preservation, and description—specifically, requirements for trusted record-making, record-keeping and records preservation systems, development of systems for managing authentic digital records that meet those requirements, and their implementation in a scalable way in resource-limited organizations. The entry concludes by outlining the present direction of the project and providing a glimpse of its future.

INTRODUCTION

InterPARES stands for International research on Permanent Authentic Records in Electronic Systems. It is a multinational collaborative research project pursuing the goal of developing the theory and methods necessary to ensure that digital records produced in databases and office systems, as well as in dynamic, experiential, and interactive systems, in the course of artistic, scientific, and e-government activities can be created in accurate and reliable form and maintained and preserved in authentic form for the use of those who created them and of society at large, regardless of technological obsolescence and media fragility.

With the financial support of the Social Sciences and Humanities Research Council of Canada, the University of British Columbia (UBC), the United States National Historical Publications and Records Commission and National Sciences Foundation, UNESCO's Memory of the World Program, and several other agencies and organizations around the world, the InterPARES project began in 1998 under the direction of Luciana Duranti, establishing its headquarter in Vancouver, Canada, at the UBC School of Library, Archival and Information Studies, and it has developed through four phases: 1998–2001, 2002–2006, 2007–2012, and 2013–2018. Over the years, it has involved investigators from numerous countries in five continents: Canada, the United States, Australia, New Zealand, the Netherlands, Belgium, the United Kingdom, Ireland, Sweden, Norway, Germany, France, Spain, Croatia, Russia, Ukraine, Italy, Turkey, China and Hong Kong, Japan, Singapore, Korea, Malaysia, Mexico, Brazil, Cuba, Argentina, Peru, Chile, South Africa, and many more.

INTERPARES METHODOLOGY

The research methodology has been based on the principles of “interdisciplinarity, transferability, open inquiry, and multimethod design.” The project is interdisciplinary in the measure in which its goal and objectives can only be achieved through the contribution of several disciplines, among which are archival science, diplomatics and records management; computer science and engineering; jurisprudence and law; music theory, composition, and performance; film theory, production, and description; dance and theater theory; geography; chemistry; archaeology; and several other hard and social sciences. In fact, in order to analyze the nature, characteristics, behavior, relationships, and process of creation of the records produced in the course of artistic, scientific, business, and e-government activities, it is necessary to gather a deep understanding of not only those activities, their purpose, their phases and the component actions, their by-products and their structure, and their context but also their technological environment and their use. In addition, to analyze the results of the case studies, methodologies developed in the context of a variety of disciplines are needed. Among these are text analysis, diplomatic analysis, statistical analysis, visual analytics, digital forensics, etc.

The ultimate goal of InterPARES is archival in nature, in that the project is concerned with the development of trusted record-making and record-keeping systems, and of preservation systems that ensure the authenticity of the records under examination over the long term. This implies that the work carried out throughout the project in the various disciplinary areas must be constantly translated in archival terms and linked to archival concepts,

which are the foundation upon which the systems intended to protect the records are designed. However, upon completion of the research, the archival systems need to be made accessible and comprehensible to records creators, organizations and institutions, service providers, IT experts, and disciplinary researchers. In other words, the research outcomes must be translated back into the language and concepts of each discipline and profession that needs to make use of them. In light of these, it was essential at the outset of the research to examine the key archival concepts that are at the core of the InterPARES research so that each field could identify the corresponding entities within its own body of knowledge.

The InterPARES research questions have epistemological roots in the humanities, specifically in diplomatics and archival science. However, the investigators involved in each research activity identify the perspective(s), research design, and methods that they believe to be most appropriate to their specific inquiry. The reason for this openness is that InterPARES is conceived to work as a “layered knowledge” environment, in the sense that some research work will build upon knowledge developed in a variety of other research projects on similar and different issues, and some will explore new issues, study entities never examined before, and develop entirely new knowledge. Each case study, as well as each of the other research activities, is carried out using the methodology and the tools that the dedicated investigating team considers the most appropriate for it. The methods used are surveys, case studies, modeling, prototyping, diplomatic and archival analysis, visual analytics, and text analysis.

INTERPARES PRINCIPLES

A few principles have guided InterPARES research through the years. The first is that technology cannot determine the solution to the reliable and accurate creation of digital records or to their authentic preservation over the long term: “organizational needs” define the problem and “archival principles” must establish the correctness and adequacy of each technical solution. A corollary of this principle is the idea that solutions to the digital records challenges are inherently “dynamic,” because of the continuing change of technology and therefore of the issues that it raises, and “specific” to the cultural, disciplinary, administrative, and legal situations in which digital records are generated, because of the contingent reasons why records are produced and kept. The second principle is that preservation is a “continuous process that begins with records creation.” Accordingly, the development of solutions to the issue of long-term preservation is dependent upon the development of guidance for the proper creation and maintenance of records that can be preserved. The third principle is that, given the fact that we cannot

preserve digital records as physical entities, but only the ability to reproduce them, we cannot verify on the records at hand their authenticity; rather, we must develop methods of records creation, maintenance, and preservation that allow us either to presume the trustworthiness of the records till proof to the contrary is established or to infer it from the integrity of the system in which the records were created and kept overtime and the chain of their custody.

INTERPARES ACTIVITIES

In order to achieve the goal of developing a body of theory and methods for digital records, InterPARES, researchers focused their initial efforts on the identification of “what constitutes a record” in each type of system being examined and in each context, and of “what record in each system and context has the force of an original.” They also studied large bodies of literature in a variety of disciplines for the purpose of defining “what a reliable, accurate, and authentic record” is in the arts, science, law, business, and administration. On this basis, they developed the requirements for the design of “a trusted record-making system,” “a trusted record-keeping system,” and “a trusted record preservation system,” using primarily modeling and the diplomatic analysis of the results of several case studies. Then, they developed “methods and procedures for the creation, maintenance, appraisal, selection, and disposition, and long-term preservation of authentic digital records,” as well as several products that could be and still are autonomously used.

At the end of the second phase of InterPARES, the need was felt to demonstrate that the findings and recommendations resulting from the research activities of the first two phases (1998–2006) were implementable in all kinds of organizations in a scalable way. Thus, the third phase of the project focused on enabling public and private archival organizations and programs with limited resources to preserve over the long-term authentic records that satisfy the requirements of their stakeholders and society’s needs for an adequate record of its past. It did so by building on the products and conceptual and methodological findings of the first two phases.

INTERPARES PRODUCTS (1998–2006)

The products of the first two phases of InterPARES were a *Framework of Principles Guiding the Development of Policies* for records creating and preserving organizations; *Guidelines for Making and Maintaining Digital Materials* for individuals and small communities of practice; *Guidelines for Digital Preservation* for archival institutions; *Authenticity Requirements* for records systems; a *Template for Analysis* of digital records; principles and criteria for adoption of *File Formats, Wrappers, and Encoding*; a

Model of the Chain of Preservation (COP) based on the lifecycle concept; a *Business-Driven Recordkeeping Model* based on the continuum concept; and a *Terminology Database*, including a glossary, a dictionary, and ontologies. These products are posted on the InterPARES website (<http://www.interpares.org>); and published in two books: Luciana Duranti ed., *The Long-term Preservation of Authentic Electronic Records: Findings of the InterPARES Project* (San Miniato: Archilab, 2005. Available online at <http://www.interpares.org/book/index.cfm>) and Luciana Duranti and Randy Preston eds., *InterPARES 2: Interactive, Dynamic and Experiential Records* (Roma: ANAI, 2008. Available online at <http://www.interpares.org/ip2/book.cfm>). The products are also discussed in articles published in a dedicated space by the journal *Archivaria*;^[1] and in writings published in a variety of venues, some of which are listed among the references and bibliography, while others can be found or cited on the project website: http://www.interpares.org/ip1/ip1_dissemination.cfm?proj=ip1 and http://www.interpares.org/ip2/ip2_dissemination.cfm?proj=ip2.

INTERPARES 1–2 CONCEPTUAL FINDINGS (1998–2006)

The InterPARES project does not study digital preservation in general, but it focuses its research on the long-term preservation of the “authenticity” of digital “records.” Thus, among the key findings of the first two phases are the concept of record in the digital environment and the concept of authenticity.

The Concept of Record

In the digital environment, an entity captured as a record presents the following characteristics: 1) a stable content; 2) a fixed form; 3) explicit linkages to other records within or outside the digital system, through a classification code or a naming convention; 4) an identifiable context; 5) five persons (i.e., an author—the physical or organizational person issuing the record, a writer—the person responsible for the record content, an originator—the person responsible for the electronic account or space where the record is made and/or saved, an addressee—the person for whom the record is intended, and a creator—the person in whose records accumulation the record exists) involved with its creation; 6) an action, in which the record participates or which the record supports either procedurally or as part of the decision-making process; and 7) formal elements, attributes, and digital components. Three of these characteristics require further explanation, that is, stable content, fixed form, and the distinction among formal elements, attributes, and digital components.

Stable Content and Fixed Form

Stable content is defined as the fact that the data and the message in the record are unchanged and unchangeable, meaning that data cannot be overwritten, altered, deleted, or added to. Fixed form means that the binary content is stored so that the message it conveys can be rendered with the same presentation it had on the screen when first saved (even if the digital presentation is different, as is the case with a record received in Word and saved in PDF). In complex dynamic and interactive systems, fixed form is a more articulated concept and involves a distinction between the “stored record” and the “manifested record,” the latter being the one we see on the computer screen. If the same content can be presented on the screen in several different ways in a limited series of possibilities, we may have either a different view of “the same stored record” having stable content and fixed form (i.e., different documentary presentations, as in the case of statistical information rendered as a pie chart, a bar chart, or a table), or “several manifested records” with stable content and fixed form derived from the same stored record. In addition, the concept of fixed form may be linked to that of “bounded variability,” which exists when there is no stored record, but only stored content data, form data, and composition data that are quite separate and only connected by a query when a user searches the system. In these cases, changes to the form of the manifested record are limited and controlled by fixed rules, so that the same query or user interaction always generates the same result, and we have different views of different subsets of content, due to the intention of the author or to different operating systems or applications (pp. 47–52).^[2]

Formal Elements, Attributes, and Digital Components

A “formal element” is a constituent part of the record’s documentary form as shown on its face. Formal elements may be extrinsic, when they determine the appearance of the record and influence its capability of reaching its purposes; or intrinsic, when they convey the action in which the record participates or to which it is linked, and its context. Extrinsic and intrinsic elements of form are listed and described in the *Template for Analysis* mentioned among the InterPARES products (see http://www.interpares.org/book/interpares_book_j_app01.pdf).

Strictly related to the concept of formal elements is the concept of “records’ attributes,” which are the identifying characteristics of each given record or of a record element in it. An attribute may manifest itself as one or more elements of form. For example, the name of the author of a record is an attribute, which may be expressed as a letterhead or a signature, both of which are intrinsic elements of documentary form, that is, record’s elements. In addition to attributes that manifest themselves in the form

of the record, that is, on the face of the record, as record's elements, every record has attributes that are implicit in other parts of the record, such as the name of the creator or of the medium, but in digital records they are also expressed, albeit outside the documentary form. Because of this, they are mostly transparent to the user and manifest themselves as metadata included in either a record profile, a topic map, or other digital entity linked to the record.

In addition to all these, with electronic records, we also have to differentiate formal elements and attributes from the record's digital components. A "digital component" is a digital object that is part of one or more digital records, including any metadata necessary to order, structure, or manifest content, and that requires a given preservation action. For example, an e-mail that includes a picture and a digital signature will have at least four digital components (the header, the text, the picture, and the digital signature). Reports with attachments in different formats will consist of more than one digital component, whereas a report with its attachments saved in one PDF file will consist of only one digital component. Though digital components are each stored separately, each digital component exists in a specific relationship to the other digital components that make up the record. Each digital component requires one or more specific methods for decoding the bit stream and for presenting it for use over time. The bit stream can be altered, as a result of conversion for example, as long as it continues to be able to fulfill its original role in the reproduction of the record. All digital components must be able to work together after they are altered; therefore, all changes need to be assessed by the creator for the effects they may have on the record.

Record Trustworthiness

In the case of the concepts embedded in the record quality of trustworthiness, the definitions adopted by the InterPARES team were not derived from traditional archival theory. The team used the definitions developed by a previous research project, commonly known as the UBC-MAS project (pp. 23–30),^[3] in the context of which "reliability" is the trustworthiness of a record as a statement of fact, that is, its ability to stand for the facts it is about, while "authenticity" is the trustworthiness of a record as a record, and refers to the fact that a record is what it purports to be and has not been tampered with or otherwise corrupted. Reliability is the exclusive responsibility of the record creator and is assessed on the basis of the completeness of the record, the authority and capacity of its author, and the degree of control exercised on the creation process. "Accuracy," a concern introduced in InterPARES research by science scholars, can sometimes be subsumed under the concept of reliability and refers to the exactness and correctness of content, mostly dependent on the competence of the author and the controls on the process by

which data are recorded and transmitted through space (i.e., between persons, systems, or applications) and time (i.e., when stored offline or when the hardware or software used to process, communicate, or maintain it is upgraded or replaced). Different from reliability, authenticity and accuracy are the responsibility of both the creator and the preserver as these depend on the controls exercised on the processes of transmission of the record across space or time.

Finally, "authentication" was defined as a declaration of authenticity, resulting either by the insertion or the addition of an element or a statement to a record. To make a distinction between authenticity and authentication was considered important because governments have been legislating about the use of digital signatures and other similar devices as means of maintaining authenticity. The team wanted to emphasize the theoretical principle that authenticity is a property of the record that accompanies it for as long as it exists, while authentication is a means of proving that a record is what it purports to be at a given moment in time.

The researchers did not elaborate further the concept of reliability, but tried to elucidate the concept implied in the definition of authenticity by dividing it into two components: identity and integrity. "Identity" refers to the attributes of a record that, together, distinguish it from other records. These attributes include the names of the persons concurring in its formation (i.e., author, addressee, writer, originator, and creator); its date(s) of compilation, transmission, and filing; the naming of the matter or action in which it participates; the expression of its relationships with other records; its digital and documentary presentations; and an indication of any attachment(s). These attributes may be explicitly expressed in a formal element of the record or in metadata related to the record or may be implicit in its various contexts.

"Integrity" is the wholeness and soundness of a record. A record has integrity if it is intact and uncorrupted, that is, if the message that it is meant to communicate in order to achieve its purpose is unaltered. This means that a record's physical integrity, such as the proper number of bit strings, may be compromised, provided that the articulation of the content and its required elements of form remain the same. Integrity may be demonstrated by evidence found on the face of the record, in metadata attesting to the responsibility for the record over time and to its technological changes, or in one or more of the record's contexts.

While in traditional archival theory, following jurisprudence, records that are relied upon by their creator in the usual and ordinary course of business are presumed authentic, with records in digital systems, the presumption of authenticity must be supported by evidence that a record has not been modified or corrupted in essential respects during transmission and maintenance. To assess the authenticity of a record, the preserver must be able to

establish its identity and demonstrate its integrity by observing the existence of certain conditions. These conditions are authenticity requirements and are used by the prospective preserver to guide the assessment of the authenticity of the records during the process of appraisal. The Authenticity Requirements developed by InterPARES can be found on the InterPARES website (http://www.interpares.org/book/interpares_book_k_app02.pdf) and in the first InterPARES book (pp. 204–219).^[4]

Many of the concepts developed by InterPARES 1–2 were incorporated in the discipline of modern diplomatics, and these are discussed in detail in the entry “Diplomatics” of this Encyclopedia.

INTERPARES 1–2 METHODOLOGICAL FINDINGS (1998–2006)

It appeared quite clear to the InterPARES researchers that the team’s understanding of the concepts of record and authenticity had a strong impact on the process of appraisal, which is inevitably influenced by the fact the objects to be selected for continuing preservation are not physical units but linked digital components whose continuing meaning is provided by attributes and whose trustworthiness relies on metadata and on unbroken control both on their transmission through time and space and on the processes of their creation, maintenance, and preservation.

Appraisal

Contrary to the archival tradition, with digital records, “authenticity” has to become one of the values assessed by the appraiser because, in the absence of an original, the future users of digital records will have only the word of the record preserver as the basis for trusting the records they will use as sources. Thus, the role of the appraiser becomes that of a neutral third party who acts as the inspector first and the warrantor later of the authenticity of the records that will be preserved.

In addition, the researchers found that several activities extraneous to traditional appraisal methodology have to be introduced in the appraisal process. Although it has been accepted for decades that archivists and records creators have to participate jointly in records scheduling for retention and disposition and that, with digital records, such an endeavor must occur as soon as possible in the life of the record, insufficient emphasis has been put by the archival community on the necessity of “monitoring” the records identified for permanent preservation on a regular basis in order to ensure that the inevitable ongoing changes of the technological environment of both the records and the creating office, and consequently of the business and documentary procedures of the creating office do not alter the records, their interrelationships, and their relationships

with the business processes to the point that a new appraisal is warranted. Monitoring is a key activity also with respect to a new concern for the appraiser: “feasibility of preservation.”

Feasibility of preservation was never a preoccupation with records on traditional media, but preservation of digital records is a very complex activity, requiring technological competence and resources that sometimes are not accessible to archival programs and institutions. Thus, the appraiser must assess the records in light of the present and future capability of the archival program or institution to preserve them. As a consequence, the appraiser may advise the creator to make certain technological choices that make the records preservable or may postpone their acquisition till such a time when preservation is feasible.

In addition, in digital systems, a record may be created for one purpose, and then subsequently used for different purposes and by different persons. Any appraisal decision should consider all uses of the record, simultaneous and sequential, by different users and by the same users, and be aware of the business processes behind them. This is necessary in order to make an informed decision about what to preserve, as well as to be able to dispose effectively of all possible copies of the records that have not been selected for preservation.

The use of records or information within records by different business processes may be desirable from the creator’s standpoint in terms of providing a degree of interoperability among the creator’s information and record systems. In such situations, the preserver should advise the creator that metadata attached to records used by many business processes must identify each relevant business process. This is critical for the creator because it ensures the authenticity of the records by establishing their identity and integrity in each context. It is also critical for the preserver who must understand all contexts in which the records were used in order to effectively undertake appraisal and also to meet the requirements for maintaining authenticity for any records acquired into the preservation system.

Preservation

In light of the principle that it is not possible to preserve an electronic record, but only the ability to reproduce it, InterPARES established that preservation of electronic records involves creating authentic copies of the records of the creator. The authenticity of these copies is guaranteed by 1) a controlled process of migration of the records acquired from the creator to the archives technological environment; 2) the accurate documentation of any change that the records undergo during such process and every time that the archives technological environment is upgraded; 3) the implementation and monitoring of privileges concerning the access, use, and reproduction of the records within the archives; 4) the establishment of

procedures to prevent, discover, and correct loss or corruption of records; 5) the establishment of procedures to guarantee the continuing identity and integrity of the records (i.e., their authenticity) against media deterioration and across technological changes; and 6) if authentication of individual records is required, the existence of rules determining responsibility for and means of authentication.

The person responsible for all these activities, the designated records preserver, has to take physical and legal custody of the records of the creators, protect them, and ensure continuous access to them. Be it an outside organization or an in-house unit, the role of the designated preserver should be that of a “trusted custodian” for a creator’s records. To be considered as a trusted custodian, the preserver must

- Act as a neutral third party, that is, demonstrate that it has no stake in the content of the records and no reason to alter records under its custody, and that it will not allow anybody to alter the records either accidentally or on purpose
- Be equipped with the knowledge and skills necessary to fulfill its responsibilities, which should be acquired through formal education in records and archives administration
- Establish a trusted preservation system that is capable of ensuring that accurate and authentic copies of the creator’s records are acquired and preserved

The authentic copies of the creator’s records are kept by the trusted custodian in a trusted preservation system, which should include in its design a descriptive system and a retrieval system. This trusted preservation system must also have in place rules and procedures for the ongoing production of authentic copies as the existing system becomes obsolete and the technology is upgraded. It should be noted that the simple fact of reproducing records in the preserver’s preservation system does not make the result an authentic copy. Such designation must be provided by the preserver’s authority.

A sustainable preservation strategy requires close collaboration between a records creator and its designated trusted custodian. It is the preserver’s responsibility to take the initiative in collaborating with the creator to establish acquisition and preservation procedures and in advising the creator in any records management activities essential to the preserver’s acquisition and preservation activities.

Archival Description

The InterPARES researchers have agreed that, no matter how careful the preservation procedures and how trusted the records custodian, ultimately, to all future users, the most important source of the authenticity of the records is “archival description.”

It has always been the function, either explicit or implicit of archival description, to authenticate the records by perpetuating their administrative and documentary relationships, but, with digital records, this function has moved to the forefront. In fact, as original digital records disappear and an interminable chain of nonidentical reproductions follows them, the researchers looking at the last of those reproductions cannot find in it any information regarding provenance, authority, context, or authenticity.

The authentication function of archival description is different from that of a certificate of authenticity because it is not simply an attestation of the authenticity of individual records, but a collective attestation of the authenticity of the records of an archival “fonds” (defined as the whole of the documents made or received by one creator and accumulated for action or reference) and of all their interrelationships as made explicit by their administrative, custodial, and technological history, the scope and content, and the hierarchical representation of the records aggregates. Also, it is different both from the identity and integrity metadata attached to individual records, which are part of the record itself and are reproduced time after time with it, and from the additional metadata attached to records aggregations (e.g., file, and series) identifying them and documenting their technological transformation. The unique function of archival description is to provide a historical view of the records and of their becoming while at the same time presenting them as a universality in which each member’s individuality is subject to the bond of a common provenance and destination. Never before archival description has had such a key function in the preservation of records.

INTERPARES 1–2 CONCLUSIONS (1998–2006)

The InterPARES project began in 1999 to find a solution to the problem of the long-term preservation of the authenticity of digital records. In its first phase, it focused on the preservation function, but the findings of its research identified the need for a holistic approach that looked at preservation as an integral part of records creation, maintenance, use, and dissemination through time. For this reason, the second phase of the project began with the analysis of the entities being created in complex systems, while still live and often incomplete, in order to understand their nature, characteristics, behavior, and use. Among the results of this analysis, there is a new diplomatic theory for interactive and dynamic records and a new archival theory of preservation, along with methodologies supporting their application.

However, the second phase of the project made it clear that, although the body of concepts, principles, and methods developed through scientific research constitutes the essential foundation and framework of best practices, any solution to digital preservation problems is situation

specific and must be devised by preservers taking into account 1) the cultural, administrative, legal, and functional context in which they operate; 2) the nature and characteristics of the organizations producing the digital material to be preserved; 3) the typology of the material produced and its documentary and technological features; 4) the limitations imposed by the available financial and human resources; 5) the organizational culture of both the producer of the material and the preserver; and 6) access to educated professionals or educational programs and resources. Furthermore, while the conceptual and methodological findings of InterPARES are equally applicable to larger and smaller organizations and programs, archives with limited resources, which often have the greatest need for assistance, will find the outcomes of the research difficult to apply without specific directions on how to move forward. Thus, a third phase of InterPARES began in 2007.

INTERPARES 3 (2007–2012)

The third phase of InterPARES aimed to translate the theory and methods of digital preservation drawn from the previous research into concrete action plans for existing bodies of records that are to be kept over the long term by archives—and archival/records units within organization—endowed with limited resources. It developed detailed knowledge on 1) how general theory and methods can be implemented in small- and medium-sized archives and units and become effective practices; 2) what factors determine the type of implementation that is appropriate for each body of records in each context; and 3) what skills professionals will require to conduct such operations.

InterPARES 3 Activities

InterPARES 3 comprised a research component, involving short-term and long-term projects (including case studies and general studies); an education and training component that consisted of carrying out, in the context of the research projects, apprenticeships, activities credited as part of coursework, etc.; and a knowledge-mobilization component, in the form of workshops, seminars, colloquia, policy manuals and other publications, public lectures, etc., that met the needs of both academic and community partners.

InterPARES 3 Methodology

InterPARES 3 carried out “action research,” that is, collaborative and pragmatic research directed toward producing solutions that were directly useful to a group of people. The research subjects were coparticipants and stakeholders in the process: jointly with academic researchers,

they defined research objectives and goals, co-constructed research questions, pooled knowledge, and developed solutions and performance tests that implemented specific strategies.

The two primary research methods were prototype development and ethnographic research. Prototype development was user-centered, collaborative prototyping exploring the interplay between theory and practice by using proof-by-demonstration through three major iterative stages: concept building, system building, and system evaluation. Ethnographic research was conducted by creators of records, their users, and archivists, who, together, formed a community of practice—the archival environment—for which social interaction created meaning and defined values. The researchers placed themselves within an archival environment to gain the cultural perspective of those responsible for records through observation of the environment with detailed description, extensive interviewing, and analysis of documentation. The researchers were divided in national teams because of their shared belief in the fundamental importance of juridical and cultural contexts in addressing each real situation. The research was structured in general studies and case studies.

The general studies were of four types: those carried out by one national team or a group of teams for the benefit of all teams (e.g., Annotated Bibliography of International Standards, E-mail Preservation); those in which all teams took part (e.g., Terminology Database); those conducted by a team that was useful for that team only (e.g., Annotated Canadian Standards); and those conducted by a group of teams sharing contextual characteristics for its own benefit (e.g., Electronic Protocol Register, procedurally required in Brazil, Italy, and Spain).

The case studies were of three types: those dealing with specific groups or types of records, those dealing with record/information systems, and those dealing with policies. The case study process was guided by a case study flow chart, which ensured that all steps were followed in the correct order, and was concluded by a final report. Each document produced in the course of a case study was structured as to form and content on the basis of a template used for all case studies. All the documents supporting the research can be found on the InterPARES 3 website: http://www.interpares.org/ip3/ip3_products.cfm?cat=2.

InterPARES 3 Key Findings

Among the many findings, the most important were management related. The case studies demonstrated that, if it is important to develop, learn, and teach how to use the structural features of an application or a system, it is even more important to understand the spirit behind those features; instead, in most cases, the training of users of acquired new applications and systems emphasizes details

of use rather than general philosophy. Users who are not acquainted with archival principles and methodologies may—intentionally or unintentionally—appropriate an application or a system “unfaithfully” more easily than records professionals. Unfaithful appropriations are likely to happen frequently with digital tools that are developed by IT experts outside the organization that will use them and often without consulting archival professionals. Interpretive flexibility or lack of it may, therefore, determine acceptance or rejection.

The case studies also showed that, when the technology is tailored to the organization, it is common to design systems primarily focused on the codified, explicit organizational knowledge because managers favor the knowledge that is incorporated in organizational artifacts like processes, structures, documents, and technology. Thus, management reporting systems, decision support systems, and electronic records management systems, are all focused on the identification, collection, and dissemination of this knowledge type. Rather, managers should foster a more complex form of organizational capital, one where a core competency for implementers requires *know-how*, the particular ability to put know-what into practice.

InterPARES 3 Products

All case and general studies are available on the InterPARES 3 website: http://www.interpares.org/ip3/ip3_products.cfm?cat=1. On the basis of the findings of these studies, InterPARES 3 developed, in addition to a variety of annotated bibliographies and the *Terminology Database*, reports on *Keeping and Preserving E-mail*, *Open Source Records Management Software*, *Criteria for Open Standard File Formats*, *Acquiring and Preserving Digital Records in Small and Medium-sized Archives*, *Digital Preservation Cost-Benefit Models*, *File Viewers*, *Metadata Application Profiles*, *Organizational Culture*, *Organizational Policy*, *Public Sector Audit Reports*, *Guidelines and Recommendations for E-mail Records Management and Long-Term Preservation*, and *Guidelines for the Long-term Preservation of the Protocol Register* (http://www.interpares.org/ip3/ip3_products.cfm?cat=1).

However, the product that best embodies the findings and recommendation of InterPARES 3 is represented by the teaching modules for in-house training programs, continuing education workshops, and academic curricula meant to form archival professionals who are competent not only to preserve over the long term the documentary heritage in digital form but also to ensure the accountability of organizations and institutions through the protection of the accuracy and authenticity of the digital information they produce. The InterPARES education modules, called “Digital Records Pathways: Topics in Digital Preservation,” were cosponsored by the Section on Archival

Education (SAE) of the International Council on Archives (ICA). Therefore, in addition to being accessible from the InterPARES website (ip3_canada_gs12_education-modules_digital-records-pathways.zip), they are also accessible on the ICA-SAE website, accompanied by a video that describes them and their use (<http://www.ica-sae.org/>).

By the time, the third phase of InterPARES was reaching its conclusions, new issues related to the authentic long-term preservation of electronic records were coming to the forefront, primarily related to the increase of records creation, maintenance, and/or preservation on the Internet and on the cloud, and to the trustworthiness of the online networked environment. Thus, a new phase of InterPARES began, called InterPARES Trust.

INTERPARES TRUST (2013–2018)

The goal of this research project is to generate the theoretical and methodological frameworks that will support the development of integrated and consistent local, national, and international networks of policies, procedures, regulations, standards, and legislation concerning digital records entrusted to the Internet, to ensure public trust grounded on evidence of good governance, a strong digital economy, and a persistent digital memory. The focus is on the relationship between organizations (both not-for-profit and for-profit) and given client groups (citizens, customers, readers, students, etc.), with client groups being concerned about the degree of “trust” they can place on records generated and/or stored and accessed on the Internet and organizations being concerned about establishing and maintaining that trust. The same themes are also addressed within the context of organization to organization and client group to client group relationships. This research will develop new knowledge on digital records kept on social media and in the cloud and on methods for identifying and protecting the balance between privacy and access, secrecy and transparency, the right to know, and the right to oblivion in globally connected networks. It will propose law reform, and other infrastructural reform, model policies, procedures, and practices, and functional requirements for the systems in which Internet providers store and manage digital records.

The partnership conducting this research comprises universities and organizations, national and multinational, public and private, in North America, Latin America, Europe, Africa, Australasia, and Asia. It also includes a “Transnational Team” comprising international organization like UNESCO and the World Bank. The list of the partners is available at <http://interparestrust.org/trust/aboutus>. The academic researchers have expertise in archival science, records management, diplomatics, law, information technology, communication and media, e-commerce, health informatics, cybersecurity, information

governance and assurance, digital forensics, computer engineering, and information policy. The empirical knowledge for this research comes from the researchers who are members of the professions having the highest stake in the questions being asked, for example, law and law enforcement, journalism, records management, finances, health, etc.

InterPARES Trust Activities

The project is divided into five research domains and five research cross-domains. The research domains are as follows: 1) *Infrastructure*: this domain considers issues relating to system architecture and related infrastructure as they affect records held in online environments. Examples of areas to be investigated include types of cloud and their reliability; types of contractual agreements and their negotiation, coverage, flexibility, etc.; costs, upfront and hidden; etc. 2) *Security*: this domain considers records issues relating to online data security, including security methods (encryption, sharding, obfuscation, geographic location); data breaches; cybercrime; risks associated with shared servers; information assurance; governance; audits and auditability; forensic readiness; risk assessment; and backup. 3) *Control*: this domain differs from the security domain in its focus on the management of digital material in online environments. It addresses such issues as authenticity, reliability, and accuracy of data; integrity metadata; chain of custody; retention and disposition; transfer and acquisition; and intellectual control and access controls. 4) *Access*: this domain researches open access/open data; the right to know/duty to remember/right to be forgotten; privacy; accountability; and transparency. 5) *Legal*: this domain considers issues such as the application of legal privilege (including the issue of extra-territoriality); legal hold; chain of evidence; authentication of evidence offered at trial; certification; and soft laws (in particular, UN standard-setting instruments)—mapping, scope, potential impact, and constraints.^[5]

The research cross-domains are as follows: 1) *Terminology*: this cross-domain is concerned with the ongoing production of a multilingual glossary; a multilingual dictionary with sources; ontologies as needed; and essays explaining the use of terms and concepts within the project. 2) *Resources*: this cross-domain is concerned with the ongoing production of annotated bibliographies, identifying relevant published articles, books, etc., case law, policies, statutes, standards, blogs, and similar gray literature. 3) *Policy*: this cross-domain considers policy-related issues emerging from the five research domains; for instance, it covers policy issues pertaining to the development and implementation of the “infrastructure” or “security” standards, or as the facilitator for the implementation of laws. In general, it addresses record-keeping issues associated with the development and implementation of policies having an

impact on the management of records in an online environment. 4) *Social issues*: this cross-domain is concerned with the analysis of social change consequent to the use of the Internet, including but not limited to the use/misuse of social media of all types, trustworthiness of news, data leaks (intentional or accidental/force majeure) consequences, development issues (power balance in a global perspective), organizational culture issues, and individual behavior issues. 5) *Education*: this cross-domain is concerned with the development of different models of curricula for transmitting the new knowledge produced by the project.

Within each domain and cross-domain, studies are carried out by multidisciplinary teams. The entire list of studies can be found on the website of the research project: http://interparestrust.org/trust/about_research/studies. Examples of studies are contract terms for cloud-based record-keeping services; ensuring trust in storage in infrastructure-as-a-service; retention and disposition in a cloud environment; modeling preservation as a service for trust; metadata, mutatis mutandis: design requirements for authenticity in the cloud and across contexts; models for monitoring and auditing of compliance in the flow from registration to archives in e-register; evaluating metadata description schemas of cultural heritage organizations in electronic environments for interoperability; comparative analysis of implemented governmental e-services; standard of practice for trust in protection of authoritative records in archives; assessment of privacy-preserving and security techniques for records management in cloud computing; the use of cloud services for records management in international organizations; security classification of records in the cloud; open government, open data, and big data on the management of digital records online; comparative analysis of the role of the records manager in an open government environment in the United Kingdom, Scotland, and Sweden; social and ethical foundations of preservation of digital historical-cultural heritage; developing model cloud computing contracts; identifying privacy concerns and attendant issues in cloud computing; putting the “fun” back in “functional”; social media use in government; and plurality and policy: designing for trust in the digital age.

The findings of the many studies carried out in the first 4 years will be the foundation on which the research team, in the final year of the project, will build the international conceptual and legal framework for the long-term preservation of authentic records in a networked online environment.

CONCLUSION

The InterPARES Project began in 1998 and is scheduled to close in 2018. It is quite possible that InterPARES Trust will not be the last phase of the project as technological

development will continue to challenge our ability to maintain and verify the trustworthiness of electronic records. Whatever the case will be, the theory, methods, and practices developed by InterPARES, which are already embedded in the disciplines of records and archival management and diplomatics, will continue to support digital record-keeping and preservation for many years to come.

School of Information Sciences, University of Pittsburgh, Pittsburgh, Pennsylvania, U.S.A.

Abstract

Information Schools (“iSchools”) address the relationship between information, technology, and people. This is characterized by a commitment to learning and understanding the role of information in human endeavors. The iSchools take it as given that expertise in all forms of information is required for progress in science, business, education, and culture. This expertise must include understanding of the uses and users of information, as well as information technologies and their applications. As of 2008, twenty-one iSchools in the United States and Canada have joined the “iCaucus,” a forum in which iSchools’ deans collaborate to further their collective interests through focused events such as the “iConference” and resources of broader interest such as the iSchools Web site.

ORIGINS

In 1988, Toni Carbo, dean of the School of Library and Information Sciences (now the School of Information Sciences) at the University of Pittsburgh, formed the “Gang of Three,” including her decanal colleagues at Syracuse University’s School of Information Studies (Donald Marchand) and Drexel University’s College of Information Science and Technology (Richard Lytle). Within the next couple of years, the dean of the School of Communication, Information, and Library Studies at Rutgers University (Richard Budd) joined the group, making it a “Gang of Four.” The Gang grew out of informal conversations at a meeting of the Association for Library and Information Science Education (ALISE). Each of the schools offered graduate Library and Information Science (LIS) and a variety of “other” programs, including undergraduate information science (IS), telecommunications, journalism, etc. The objective was to share information and to foster the development of a community of colleagues addressing such questions as “How do you explain IS to your provost?” The Gang met informally into the mid-1990s.

In 2001, the group was reconstituted under Toni’s leadership at a meeting in Pittsburgh. Participants included deans from Syracuse University (Raymond von Dran), Drexel University (David Fenske), the University of Washington’s Information School (Michael Eisenberg), and the University of Michigan’s School of Information (John King). With that meeting, the “Gang of Five” was formed.

Beginning in 2003, Gang membership grew with the addition of deans from the Graduate School of Library and Information Science at the University of Illinois, the School of Information and Library Science at the University of North Carolina, the College of Information at Florida State University, the School of Informatics at Indiana University, and the School of Information at the

University of Texas, bringing it to the “Gang of Ten.” By this point, the informal name was becoming unwieldy and a bit inappropriate, particularly as continued growth was anticipated. Through the leadership of deans John King, the late Raymond von Dran, and Michael Eisenberg, the group’s agenda became more focused on building a sense of identity and community among the “information schools,” or “iSchools.”

Typically, the group met twice per year. Meetings, hosted by one of the deans, included private discussions among the deans as well as open conversations with faculty of the host school, and usually an informal reception or lunch. During the deans-only sessions, the agenda focused on challenging administrative, programmatic, and planning issues, in addition to the continuing interest in explaining IS better to our non-IS colleagues. The sessions also provided an opportunity to learn about the curriculum and research of each school. An early goal was to nurture the development of a critical mass of faculty across the schools to undertake collaborative research.

The group was formally named “the iSchools Caucus” (more casually referred to as the iCaucus), and its membership grew rapidly with the addition of:

- The School of Communication, Information, and Library Studies
Rutgers University (rejoining)
- The School of Information
University of California, Berkeley
- The Donald Bren School of Information and Computer Sciences
University of California, Irvine
- The Graduate School of Education and Information Studies
University of California, Los Angeles
- The College of Information Sciences and Technology
Pennsylvania State University

- The College of Computing
Georgia Institute of Technology
- The School of Library and Information Science
Indiana University
- The College of Information Studies
University of Maryland
- The Faculty of Information
University of Toronto

And in 2008, two more institutions joined:

- The Heinz School
Carnegie Mellon University
- The School of Information Systems
Singapore Management University

As a board member of the Computing Research Association (CRA), King introduced the iSchools Caucus to the CRA IT Deans Group, founded in 2000 at the Snowbird meeting and chaired by Peter Freeman (Georgia Tech). In 2008, the name of the CRA group was shortened with majority approval to the “CRA Deans” group. The CRA Deans group provides a broad forum for leaders of IT schools, colleges, and institutes to share experiences, strategies, opportunities, and concerns. It illuminates issues and seeks common ground leading to a coherent and unified voice for the academic and research communities, and to the general public. A substantial majority of the iSchool deans have joined the CRA Deans group in order to assure that information-related issues are appropriately reflected in the group’s evolving agenda.

MOTIVATION

The emergence and evolution of iSchools was triggered by the explosive growth in digital information. In a 2003 study,^[1] Peter Lyman and Hal Varian estimated that about 5 exabytes (5×10^{18}) of new information was generated in 2002 worldwide, with a growth rate of about 30% per year. They note that 5 exabytes “is equivalent in size to the information contained in 37,000 new libraries the size of the Library of Congress book collections.” A 2007 study by IDC^[2] concluded that the worldwide production of information in 2006 exceeded 161 exabytes, increasing at a compound annual growth rate of 57%. While only a small fraction of this information is accessible online (<2% by some estimates), it still represents an enormous and increasing amount of information that presents major challenges (and opportunities) in information management, access, and preservation.

Marcia Bates defines “the *domain* of information science [as] the universe of recorded information that is selected and retained for later access,” and posits that

applied IS is “primarily concerned with the form and organization of information, its underlying structure, and only secondarily with its content.”^[3] Add to this the study of human use of information and the design and development of the technological tools to utilize information, and an understanding of the domain of the iSchools emerges. Bates succinctly states these through three driving questions:

- What are the features and laws of the recorded-information universe? (physical question)
- How do people relate to, seek, and use information? (social question)
- How can access to recorded information be made most rapid and effective? (design question)

The iSchools are interested in the relationship between information, technology, and people. This is characterized by a commitment to learning and understanding the role of information in human endeavors. The iSchools take it as given that expertise in all forms of information is required for progress in science, business, education, and culture. This expertise must include understanding of the uses and users of information, as well as information technologies and their applications.

(From the iSchools Web site <http://www.ischools.org>, 2008.)

POSITIONING

The “identity debate” has a long tradition in information studies and it influenced the formation of the iSchools as a group. It takes on many forms and has multiple dimensions. Wanda Orlikowski and Suzanne Iacono^[4] argued for a theoretical focus on IT artifacts and laid out five relevant conceptualizations:

- Tool view (e.g., a productivity enhancer).
- Proxy view (e.g., surrogate measures such as return on investment).
- Ensemble view (e.g., technology embedded in a socio-economic system).
- Computational view (e.g., models and algorithms).
- Nominal view (e.g., studies of broad impacts such as outsourcing).

Ron Weber^[5] posited, “the identity of a discipline is established through the contributions it makes to theory.” He went on to suggest that he could find “only one class of phenomena for which theories sourced from other disciplines seemed deficient—namely, phenomena associated with building conceptual models and designing databases.”

Another facet of the identity discussion has been the attempt to draw boundaries. Izak Benbasat and Robert Zmud^[6] summarized some of this line of thought as placing claim on three necessary and sufficient criteria: a central character, distinctiveness, and temporal continuity. They argued that a dominant design for the information systems discipline “has yet to be realized” and that this hinders the field’s legitimacy. They affirmed the centrality of the IT artifact, placing the notion in a broad context including understanding capabilities and practices, human behaviors, usage, and impacts.

Robert Galliers^[7] pushed back on Benbasat and Zmud, arguing that boundaries and disciplinary cores emerge naturally as a field evolves. In IS, forces shaping this evolution include such topics as the digital divide, globalization, and IT in the developing world, resulting in a broadening of the locus of study to include societal, policy, and ethical issues. He suggested adopting a “transdisciplinary” perspective on the field of IS. Table 1 adapts Galliers’ characterization for IS to the domain of the iSchools.

DeSanctis^[8] reflected on the increasing pervasiveness of information technology, observing that “knowledge and creative use are no longer the sole domain of specialists.” This has shifted the dominant functional role of information professionals from development to leadership and support, and put many in strategic business positions. As information professionals take on these new roles, technical skills must be supplemented with new competencies in human relations and organizational effectiveness. As DeSanctis observed, “the institutional paradox for IS is that the domain has become of interest to many faculty groups yet the sole purview of none.” While, perhaps, not the *sole* purview, this is, most certainly, the *primary* purview of the iSchools. Rather than focusing on a bounded “domain,” DeSanctis argued for a “focus on the questions” and observed that these have historically generated excitement and impact in IS.

Daniel Robey^[9] continued the call for a “more flexible identity for IS” that avoids “the lure of a dominant research paradigm.” He suggested a pursuit of “pragmatic legitimacy” that casts IS as a “valued partner in intellectual exchanges with our external constituents: the governing bodies, business executives, university officials,

and scholars from other disciplines who are the key actors in IS’s organizational field.”

John King and Kalle Lyytinen^[10] acknowledged that the IS field lacks a theoretic core and has been “haunted by feelings of inadequacy” for 30 years. They proposed an alternative model for establishing legitimacy, grounded in three drivers:

- Salience of issues studied.
- Production of strong results.
- Maintenance of plasticity.

They offered an alternative view of the core of the discipline as a “market of ideas” where the IS field is defined as “the study of the design and management of information and associated technologies in organized human enterprise.” Rather than accepting the argument that theory should provide the foundation, they suggest, rather, that theory “to the extent that it has a role, is in the service of producing strong results.”

King^[11] sums up this discussion of identity, observing that iSchools

straddle the academy’s ancient engagement with information and the contemporary challenges of ubiquitous information affecting all aspects of society.... The [iSchool] movement is emergent; its equilibrium can only be found in an essential tension among competing visions in a world of rapid technical and social change. [iSchool] identity is elusive and will remain so for the foreseeable future.

EMPOWERMENT

Studying at an iSchool immerses students in this dynamic and emerging “iField,” where they confront the issues, opportunities, and challenges of an information society in the twenty-first century, in all their richness, controversy, and ambiguity. The iField addresses the fundamental issue of harnessing the incredible flow of information for the betterment of humanity.

The iField also empowers people in other fields to create, find, store, manipulate, and share information in useful forms. It may be unique in that, despite its elusive core, its subject, information, is at the heart of what individuals, organizations, and societies need in order to advance human endeavors, from acting to zoology. The iField’s most visible and viable outcome is the delivery of the right information at the right time to the right people in the right form.

ORGANIZATION

The iSchools were founded as a consortium to establish broad recognition of the iField and its importance to

Table 1 IS as a transdisciplinary domain.

	Disciplinary	Trans-disciplinary
Boundary	Organization	Society
Central artifact	IT	People/information
Focus	Inward	Outward
Scope	Narrow	Broad
Reference disciplines	Org-behavior, Computer science, etc.	IS, LIS, telecommunications
Properties	Defined	Emergent
Inter-disciplinary	A threat	An opportunity

society. In this role, they sought to position a group of academic institutions to identify, clarify, and speak to the major issues, challenges, and driving questions at the nexus of information, technology, and society. While a relatively small number of universities took the lead in establishing an organization with this goal, those who share the goal and contribute to its achievement go far beyond the small collection of organizers. The defining characteristics of iSchools (whether iCaucus members or not) include:

- An interest in the relationship between information, technology, and people.
- A commitment to learning and understanding the role of information in human endeavors.
- A recognition that expertise in all forms of information is required for progress in science, business, education, and culture.
- A belief that this expertise must include understanding of the uses and users of information, as well as information technologies and their applications.

The collective efforts of the iSchools (e.g., the iConference, the Web site, and special projects) are managed by the iCaucus. Members of the iCaucus pay an annual fee and have one vote on iCaucus decisions. The iCaucus charter specifies its membership criteria. Candidate memberships are reviewed by a membership committee and voted on by the full iCaucus membership. While not rigid, iCaucus members are expected to have substantial sponsored research activity, to engage in the training of future researchers (usually through an active, research-oriented doctoral program), and a commitment to progress in the information field. Each iSchool's representative to the iCaucus (usually a dean) is expected to report to the chief academic officer of the parent institutions.

The iSchools sponsor the iConference as a forum for faculty, students, and researchers to share their work and to develop their extended network of colleagues. The conference runs 3–4 days and the program typically includes a doctoral colloquium, poster and paper sessions, panels, roundtables, and social events. The first iConference was held at Penn State in September 2005.^[12] Subsequent iConferences were hosted by the University of Michigan and UCLA, with the 2009 iConference being hosted by UNC Chapel Hill.

VISION

As a relatively straightforward example, consider an iSchool's approach to information assurance, an issue of contemporary salience, for which we seek to produce strong results while adapting to changing conditions. When viewed as a technological issue, scientists and

engineers are likely to focus on topics such as cryptography, steganography, public key infrastructure, and intrusion detection, or, in other words, technical areas in which they are likely to have significant interest and expertise. The same set of issues viewed from the perspective of librarians may be more likely to draw attention to questions of identification, authentication, provenance, and access. A social scientist, on the other hand, may focus on issues of confidentiality, authentication, privacy, and integrity. So who is right? Clearly, they all are. Information assurance is a multidisciplinary problem with extraordinarily complex and interrelated technical, policy, and social challenges. An iSchool provides the venue that enables scholars from a variety of contributing disciplines to leverage their individual insights, perspectives, and interests, informed by a rich, "transdisciplinary" community.

But transdisciplinary collaboration is not a natural act. Not only does each discipline bring to the table a set of values, goals, models, economics, and ethics that have evolved slowly and in relative isolation over an extended period of time within their discipline, but also they must interact with and respond to the interests of external bodies. These are not always aligned in ways that foster rapid agreement.

- Values—some will argue that strength is derived from information access, while others contend that power is founded on information control.
- Goals—some argue for increasing safety and security by way of imposing limits and locks, while others opine that justice and accountability are advanced through dialogue and debate.
- Models—some see information access primarily as a societal responsibility, where others view it dominantly as a business opportunity.
- Economics—information is expensive to create and publish, but cheap to replicate and distribute.
- Ethics—some argue that ethics are trumped by the realities of the real world, while others rebut that they are motivated by that very same world.

The complex interaction among the disciplines, when allowed to play out in an iSchool, provides a rich environment for the education of information professionals. Exploiting the very tensions that arise among the various constituencies enriches the creative insight of each. Among the issues feeding such creative dialogue are topics such as:

- Intellectual property rights and its relation to fair use.
- Open, extensible systems as an alternative to proprietary, closed designs.
- Access to publicly funded information balanced against legitimate security requirements.
- Assuring ethical public policy when the need for expediency feels overwhelming.

- Recognizing the need for both selective government secrecy and accountability through open records.

While the resolution of these issues is ultimately expressed in society's evolving social contract, the iSchools serve a vital role by:

- Preparing the next generation of information professionals.
- Informing the relevant social and political structures regarding the implications and use of information technologies.
- Assuring that debates surrounding the development of policy and law are properly informed by sound scholarship.
- Advising society of the potential consequences of policy alternatives.
- Interpreting opportunities and implications of policy alternatives.
- Remaining, themselves, engaged students of a highly dynamic landscape of change.

So what is an iSchool in the twenty-first century? Informed by decades of debate and responding to exceptionally rapid changes in technology and uncertainty in public policy, iSchools foster the development of an intellectual space where true interdisciplinarity plays out. In so doing, they introduce a range of challenges to traditional university structures and practices regarding organizational boundaries, promotion and tenure policies, doctoral education, research legitimacy, etc., as they create an environment where issues of information are addressed systematically, regardless of disciplinary heritage or presumed "ownership." In this way, iSchools respond to the salient issues of the time by stressing the production of strong results. They are in a constant state of adaptation within their core competencies, while building necessary bridges among disciplines. The iSchools recognize that the near-term future will be shaped largely by industry, so their applied research agenda is strongly influenced by these emerging needs and directions. But the iSchools lead industry and government in the study of timeless, recurring, theoretical questions, and educate the next generation of information professionals who will shape the future of a global information society.

RECOGNITION

Von Dran was a dynamic and powerful force in both the development of the School of Information Studies at Syracuse University and the formation of the iSchools movement. In his own words,

Information schools are advancing a common notion that it's *information*, and not simply the technology, that is the

driver. The information field must harness a number of disciplines and approaches that critically affect the relevance, timeliness, accessibility, and quality of information. These schools bring together the various aspects of technology, management, policy, and usability, among others, for the benefit of people everywhere.

In his honor, the iSchools have established an award to recognize others who have demonstrated Ray's commitment to excellence and leadership. The award is presented at the iConference and includes a monetary award and an opportunity for the award winner to share his or her vision of the challenges and opportunities confronting the information profession to conference participants.

ACKNOWLEDGMENT

This entry is dedicated to the memory of Raymond von Dran, Dean of the School of Information Studies, Syracuse University, 1995–2007. The author gratefully acknowledges the assistance of Toni Carbo and Jonathan Grudin in reconstructing the historical timeline for the iSchools and of Maeve Reilly for improving the readability of this entry.

Israel: Libraries, Archives, and Museums

Snunith Shoham

Silvia Schenkolewski-Kroll

Department of Information Science, Bar-Ilan University, Ramat Gan, Israel

Abstract

This entry presents three cultural institutions—libraries, museums and archives—in Israel, against the backdrop of the international Jewish Diaspora and the establishment of the State of Israel in 1948, as an immigrant absorbing nation, where foreign powers previously ruled (the Ottoman Empire until 1917 and the British Mandate from 1917 to 1948). In this historical and governmental context (with its legislative, municipal, social and cultural ramifications), the entry traces the development of these three institutions and paints an up-to-date portrait of their current situation.

INTRODUCTION

After the failure of the rebellion against the Romans and the fall of Jerusalem in 70 C.E., many Jews were dispersed to foreign lands and only a few remained in *Eretz Yisrael* (The Land of Israel), living under rulers who changed several times over the centuries. From 1517 until 1917, Eretz Yisrael was part of the Ottoman Empire. Following World War I, the British received a mandate to rule in Eretz Yisrael, which continued until May 15, 1948 (as a result of a United Nations decision made in November 1947) (see Fig. 1).

Modern Israel is a country that absorbs Jewish immigrants. It developed primarily through five waves of pre-State immigration, which brought some 450,000 immigrants to Israel from 1882 to 1948 and a mass immigration from Eastern Europe and the Arab countries after the Holocaust and the establishment of the State of Israel. The Jewish population has grown from 649,000 in 1948 to 5,567,000 in December 2008.^[1,2]

The Arab sector in Israel numbers 1,487,000 people, who are 20.2% of Israel's population. There are also 319,000 non-Jewish immigrants and 200,000 foreign workers, who are not citizens, living in Israel.

This entry will survey the development of libraries, archives, and museums in the State of Israel and present a current portrait of these cultural institutions.

LIBRARIES

Historical Perspective

During the years when there was no autonomous Jewish rule in Eretz Yisrael, libraries existed in synagogues and study houses (*Beitei Midrash*), as well as private collections. In the nineteenth century, non-Jewish communities

also maintained libraries in Eretz Yisrael, mainly in Jerusalem. These were owned by foreign institutions and mainly contained books about Eretz Yisrael for the use of archeologists, historians, and tourists. There were also theological collections and devotional literature in monastery and church libraries.

The first library in Eretz Yisrael to include secular literature was the one established in the Jewish hospital in Jerusalem in 1854, which received a delivery of books in several languages, sent from Paris. In 1870, the first agricultural school, Mikve Israel, was founded, including a library that began with 300 volumes and grew to approximately 3000 by the end of the century.

The last quarter of the nineteenth century saw the opening of the first secular public libraries in Jerusalem (the Montefiore Book Collection in 1874), Rishon Lezion (1883), Jaffa (1886), Safed (1891), *Sha'ar Zion* Library in Jaffa (1891), the Abravanel House Library in Jerusalem in 1891 (which later became the National Library), Petah Tikva (1892), Zichron Yaacov (1895), Hadera (1899), and Sejera (1902).^[3] During the period of the British Mandate, there was not one Jewish town or village in the Land of Israel that did not have a library of some type, although many were unable to maintain an uninterrupted existence.^[4] These libraries were established, first and foremost, because the ideology of the Jewish national revival movement strove, among other things, to create a society with modern goals for education and cultural creativity.^[4] Other contributing factors were the tradition of study and the unique status of books in Jewish culture. The Enlightenment Movement led to the development of cultural and educational institutions and the establishment of Hebrew newspapers. Indeed, the founders of many libraries in Israel were teachers and groups of educated people.

The nineteenth century also saw, for the first time, the establishment of libraries as part of *educational institutions*, though some of these also served the general public.

Fig. 1 Map of Israel.

Source: CIA *The World Factbook*.

During the 1890s, libraries were set up in schools for the first time, in Petah Tikva, Gedera, and Sejera. The collections in these school libraries reflected the education that the schools provided and educational trends at that time. They generally included religious literature and, sometimes, secular Hebrew literature. In some libraries, French literature was also included.

The General Federation of Labor of the Hebrew Workers in Eretz Yisrael, or *Histadrut* partially

compensated for the lack of the autonomous municipal governments that were responsible for the establishment of public libraries throughout the Western world. The *Histadrut* concerned itself not only with workers' interests but also with the provision of culture, and regarded libraries as a basic component of social, educational, and cultural life. Among other things, the *Histadrut* set up workers' libraries in many urban communities, mainly beginning in the 1920s and 1930s. Earlier instances of this phenomenon involved small workers' associations that set up small "workers' clubs" and "reading rooms" in the late nineteenth and early twentieth centuries.

In 1892, the Jerusalem bureau of the B'nai B'rith organization set up the Abravanel House Library. This library initially contained *belles lettres* as well as theoretical and scientific literature and soon adopted the goal of amassing *all* Hebrew works and material pertaining to the Jews of Eretz Yisrael, some of which had also been published in foreign languages. Hence it gave priority to books on Judaism and rare books, and issued appeals to Diaspora Jewry to establish depositories for the books of the Jewish people.

It was thus, at the initiative of a few individuals, that the nucleus of the National Library of Israel was formed. The first to call for the creation of a national library that would amass books in the areas of Judaism and the Land of Israel came from Rabbi Yehoshua Heschel Levine of Volozhin, whose article on the topic appeared in the Jerusalem periodical *Havatzelet* in 1872. The Hibbat Zion movement in Odessa also advocated the creation of a national library. Among those active in this connection was a Hibbat Zion member Dr. Joseph Chazanowicz of Bialistok, who, after visiting Eretz Yisrael in 1890, decided to devote his life to the collecting of books. During 30 years of activity he collected 16,000 books, many of them rare, and transferred them to the Abravanel House Library.^[5]

In 1920, the library was acquired by the World Zionist Organization and, for the first time, a professional librarian, Dr. Shmuel Hugo Bergmann, was appointed as its director.^[6] In 1925 with the establishment of the Hebrew University, the first university in Eretz Yisrael, it was decided that the library would serve as a national and university library. The library also served as a public library, open to all, thus filling a void that had previously existed in Mandatory Eretz Yisrael.

The National Library

Since its establishment, *The Jewish National and University Library* has served a threefold purpose. It is the national library of the State of Israel, the national library of the Jewish people, and the central library of the Hebrew University. However, there are plans to change this and the process of reestablishing the national library as an organizationally and financially independent body has

Fig. 2 National Library of Israel.
Source: National Library of Israel.

begun. A law passed in November 2007 delineates the transition process and the goals of the National Library. In accordance with the law, the National Library has been as a public-service corporation since June 2008 but remains a subsidiary of the Hebrew University. When the transition process is complete, within 3 years, it will no longer be a subsidiary of the Hebrew University but rather an independent organization known as the National Library (Fig. 2).^[7]

The library serves as a depository for all books published in Israel. In 1953, the first legislation was passed requiring that a copy of all publications be submitted to the National Archive, to the Knesset (parliament) Library, and to the National Library. In 2000, the law was expanded to include publications that are not printed on paper. The library also collects material about Israel, the Jewish people, and Judaism, as well as material written in Hebrew script and in other Jewish languages (Yiddish, Ladino, etc.) from every place and time. In addition, it has collections of rare Judaica and Hebraica, manuscripts and incunabula amassed from all corners of the world. The library also contains one of the largest and best-organized collections on Arab and Islamic subjects in the Middle East.

The library contains over 5 million books and periodicals, as well as many thousands of items in special collections, such as manuscripts and archives (see the section on Archives), maps, and music recordings. Most of the collections are in closed stacks. The library also has about 11,000 manuscripts, 9000 of them in Hebrew and the rest in Arabic. The library's Paleography Project is conducting research on the codicology and paleography of dated medieval Hebrew manuscripts. The library also houses the Institute of Microfilmed Hebrew Manuscripts, which has undertaken to collect microfilm copies of all Hebrew manuscripts extant in public and private collections. Over 60,000 items, representing 90% of known Hebrew manuscripts, are already available to scholars.

Among the library's special collections are the Depository Collection of the United Nations, which contains publications of the United Nations and documents of the League of Nations; the European Union Depository Collection.

The Jewish National Library publishes the *National Bibliography (Kiryat Sefer)*, an annotated bibliography that contains entries for all works on Israel, Jews and Judaica, published in Israel and abroad. The library also publishes a bibliography of periodical literature called *Index of Articles on Jewish Studies (RAMBI)*, which covers journals and periodicals from all parts of the world.

Another research tool prepared by the library is a retrospective bibliography of books printed in Hebrew characters, *The Bibliography of Hebrew Books, 1472–1960*. It also provides online links to two other indexes: The Index to Hebrew Periodicals and the Index to Hebrew Israeli Newspapers, which are prepared by other Israeli libraries. The library has begun a digitalization project that includes making the library's collection of Jewish marriage certificates, manuscripts of the Mishna and Talmud, ancient maps of Jerusalem, official records of Jewish communities, the Einstein archive and historical Jewish and Israeli newspapers, etc. available to all on its Internet site: jnul.huji.ac.il.

Academic Libraries

When the State of Israel was proclaimed in 1948, it had two universities: the Technion Israel Institute of Technology, founded in Haifa in 1924, and the Hebrew University of Jerusalem, established in 1925, on Mount Scopus. Since then, six additional universities have been established: the Weizmann Institute of Science (1949), Tel Aviv University (1953), Bar-Ilan University (1955), the University of Haifa (1963), Ben-Gurion University of the Negev (1966), and the Open University (for distance education, 1976). Today there are also 30 academic and regional colleges, including some private institutions, and 25 teachers'

training colleges. In recent years many colleges have been upgraded and have begun to grant academic degrees.

The Israeli universities do not use a uniform library model. Whereas the University of Haifa and Ben-Gurion University have one central library, other universities, for example, Bar-Ilan University and the Technion, have many departmental libraries. Others, like the Hebrew University, also have large division libraries.

Interuniversity cooperation

In 1969, the government established the Israeli Standing Committee of the National and University Libraries (SCONUL), a voluntary forum for discussing problems of policy and planning. SCONUL initiated an interlibrary loan system among the universities and set up a group of committees to deal with cataloging, acquisition, reference, periodicals, and circulation.

In 1979, the Hebrew University developed a library automation system (ALEPH) that was adopted as the software program of the university libraries in Israel. The Grants Committee of the Israel Council of Higher Education has also contributed to this by subsidizing the university libraries' participation in ALEPH. Today, all the catalogs of the universities and the majority of the colleges in Israel are on the ALEPH network. The *Israel National Catalog* currently lists over 8 million books, periodicals, and audiovisual items in 65 university, college, and specialty libraries. The catalog uses MARC format and ALEPH-500 software. All Unicode characters are supported.

In 1998, the university heads established a consortium framework, the Israel Center for Digital Information Services (MALMAD). MALMAD's main function is the acquisition, licensing, and operation of information services for all the Israeli universities. It makes databases, directories, and digital journals available to the universities.^[8]

Public Libraries

In the 1960s, just 15 years after the establishment of the State of Israel, there was an attempt to change the educational system in order to promote social equality and integration in the new society, which included immigrants from various cultures. In this context, the government began to address the issue of public libraries.

In 1962, a Department of Libraries was created in the Ministry of Education for the purpose of encouraging public libraries, which more than half of the communities lacked. Furthermore, few of the existing libraries met the criteria for proper service in terms of collections, opening hours, and staffing.

In 1975, the Knesset passed the Libraries Law which did not mandate the establishment of a public library in every town but did set criteria for recognizing a library as

"public" and the resultant eligibility for some degree of funding from the national budget. The law also established the Council for Public Libraries, which advises the minister regarding implementation of the law and submits its own proposals to him.

When the development of the libraries began, there was a gradual but steady increase in the percentage of registered readers using public libraries. In 1985, 25% of all residents of the state were registered in libraries. Since that time, there has been an ongoing, gradual decline in the number of readers and in 2007 approximately 16% of residents are registered in public libraries.

In 2007, all Israeli public libraries together circulated 8.7 million items and 3 million users visited their reference rooms; of these, 900,000 were Internet users. (Information from the Department of Libraries, Ministry of Science, Culture and Sport.) As of today (2008), there are 212 administrative library units in Israel, which together encompass 862 service points (including all branches). The library units include 44 regional libraries and 50 urban units located in community centers. Another 120 have a double function, serving as both regional and school libraries; of these, 80 libraries operate in elementary schools and 40 in high schools. The regional libraries, which began in the 1960s, are now being transformed to conform to a new organizational conception, adopted in 2006. Instead of having a small library in every town or village, larger libraries are being formed to serve several communities, alongside central libraries that serve not only the public but also an educational institution.

A vast majority of the libraries' current collections are in Hebrew, even though Israel is an immigrant society. For many years, a melting-pot conception of immigration prevailed in Israel. A survey done in 1980, found that only 11% of all the collections in the public libraries included material in foreign languages, and most of it was not in dynamic collection.^[9]

During the 1990s, a different concept of immigration developed in Israeli society and it came to be understood that immigrants have an inner need to preserve their mother tongue and cultural heritage. In the library field, this was manifested in a greater emphasis on materials in languages spoken by the immigrants living in a given community. To aid the libraries in this regard, a central library for Russian was set up in 1989 to provide libraries throughout the country with long-term loans of books in Russian. There are also central libraries for books in French, established in 1986, and Spanish, established in 2003.

Most libraries do not have nonbook collections. Only a few libraries have audio or video collections, but in the last decade libraries have begun to make computers available to the public, offering multimedia materials, games, and access to the Internet. Currently, computer stations are available in half of the libraries (see Figs. 3 and 4).

Fig. 3 Computers in Holon Mediatheque (Public Library).
Source: Central Library in Holon.

Funding of the Israeli public libraries is the responsibility of the local governments, which determine their budgets, and there are substantial differences in amounts allocated by the different local authorities. In addition, the libraries receive some support from the Ministry of Culture, though the proportion of its budget allocated to libraries has declined over the years and was about 10% of the total budget for libraries. On July 16, 2007, the Knesset passed a law that set a scale for the gradual increase in the State's budgetary allocation for the libraries, beginning in 2008. In 2008, the proportion of the libraries' budget allocated by the government rose to about 15%. By 2013, the State should be funding half of the libraries' budgets. Over the past 25 years, 70% of libraries in the urban communities have resorted to collecting fees for subscriptions to lending services. This source constitutes 5% of the libraries' budget. The new law makes receiving the higher allocation conditional on discontinuing the collection of subscription fees. Most libraries did indeed stop collecting fees as of January 2008. This is probably the reason for the increase of approximately 20% in the number of readers and circulation in 2008.

The Israeli Center for Libraries

In the 1960s, a decision was made to learn from the Scandinavian model of a public library system. This led, in 1965, to the creation of the Center for Libraries that

Fig. 4 Seating Area in Holon Mediatheque (Public Library).
Source: Central Library in Holon.

provides central services to the libraries. The Center provides central cataloging services to public and school libraries in Israel (now in electronic form), publishes professional literature and tools for librarianship. It also offers an array of courses, and training; organizes annual conferences; serves as the Israeli representative of ISBN; and provides consultancy services to libraries on the management, architecture, equipping, and furnishing of libraries, as well as supplying products and services for the encouragement of reading.

School Libraries

During the first years of its existence, Israel absorbed massive waves of immigration, and the focus in those years was on the establishment of a school system. For a long period, many schools had only a small number of books or small library collections. Only in the 1970s, with the increased awareness of the importance of school libraries, did the creation of school libraries begin.

In 1988, the Department of Libraries of the Ministry of Education and Culture assumed responsibility for dealing with school libraries and this led to the intensified cultivation of existing libraries and establishment of new libraries in the schools that still lacked them. The findings of a survey done by the department in 1993–1994 showed a substantial increase in the number of school libraries in Israel, with libraries functioning in 87% of the high schools and 83% of the elementary schools. During 1992–1994 an average of 66 new libraries were established each year.^[10] Since the early 1990s, the concept of the library as a “resource center” has developed and there has been a countrywide effort to make the libraries into resource centers.

Today, there are a total of 2414 elementary schools in Israel (in the educational streams of all sectors, including small, private ultraorthodox schools) and 1941 high schools.^[11] Currently, 20% of the elementary schools still lack libraries, as do 10% of the high schools. Undoubtedly, the situation of the high school libraries is better than that of the elementary school libraries, although more books are lent for free reading in the elementary schools reflecting the decline in reading as students get older and the greater emphasis that elementary schools place on encouraging reading.

The Ministry of Education’s regulations require that there be a librarian in every high school but not in every elementary school. Therefore, elementary school principals can decide whether or not there will be a librarian in their school and what the scope of the librarian’s activities will be.

Special Libraries

In Israel approximately 600 special libraries are operated by government agencies, institutes and research centers, hospitals, museums, banks, corporations, and enterprises.

One special library is the *Library of the Knesset*, which began to operate in 1950. Its main role is to serve the members of Knesset and support the legislative process. To this end, it includes an *Information Center*, which was set up in 1973, and prepares surveys on various subjects, at the request of members of Knesset and their aides or of the various Knesset committees and bureaus. In the framework of the *Freedom of Information Law* (1998), which stipulates that it is the right of every Israeli citizen or resident to receive information from a public authority and defines information as “any information that exists within a public authority and is written, recorded, filmed, photographed or computerized,” the library provides citizens with information on the activities of the Knesset and its committees, on bills presented and laws enacted. The information is provided by means of telephone, mail, fax, and the Knesset’s Internet site (<http://www.knesset.gov.il>), which is operated by the library.

Medical libraries are a prominent group of special libraries. At present, there are approximately 80 medical libraries in Israel of various kinds. Israel has four medical schools (at the Hebrew University, Tel Aviv University, the Technion, and Ben-Gurion University), each with its own large medical library. In addition, all hospitals have medical libraries, some are large but others employ only one person. Twenty-two of the medical libraries are organized into two regional networks, centered around university libraries. The network began its operation in 1975, aiming to promote interlibrary cooperation based not only on the sharing of resources but also on specialized biomedical information and professional skills. The academic medical school libraries are responsible for coordinating the work of all the medical libraries in their region.^[12] The consortium of medical libraries fills the following functions: 1) joint purchase of online data bases and e-journals; 2) interlibrary loans—supplying documents and scientific publications to libraries, using the same software for transmitting documents; and 3) holding seminar days and training sessions.

Another special library is that of the Standards Institution of Israel, which has an extensive standards and technical documentation library (<http://www.sii.org.il>), where the Israeli standards and specifications are collected in both electronic and print formats. There is also a vast collection of foreign standardization documents, including international standards, as well as guidebooks and databases in the field.

The Arab Sector

The Arab sector accounts for 20% of the population. They live in 123 settlements and consist of five different groups: Moslem Arabs (58%), Moslem Bedouins (15.4%), Christian Arabs (15%), Druze (8.8%), and Circassians (2.8%). Eight mixed towns or cities are home to 35% of the Arab

population while the remainder live in exclusively minority towns (88) and villages (35).

Academic and research libraries

Five universities—the University of Haifa, Hebrew University, Tel Aviv University, Ben-Gurion University and Bar-Ilan University—offer studies in Middle Eastern and Islamic Studies and Arabic language and literature. Each of these universities maintains large academic collections of literature and books in Arabic to serve the academic departments.

The University of Haifa has a large Arab student population and its library is used by Arab teachers and high school students in the region. Therefore, it has a policy of building a more comprehensive collection of Arabic books on all subjects.^[13] It also has a collection of children's literature in Arabic.

Israel also has three colleges for training Arab teachers: the Academic Center for Training Arab Teachers (part of Beit Berl College), the Arab College in Haifa, and the Islamic College in Baka al-Garbia. Each of these has a library that provides resources for instruction. Not many books in Arabic are published in Israel, a small amount of fiction and a few scholarly works. Therefore, the librarians have to travel to the annual book fair in Cairo, where they can order books that have been published in Egypt, Jordan, Saudi Arabia, Kuwait, Morocco, and Sudan.

There are also research institutes in related fields, among the better-known ones being the Harry S Truman Research Institute for the Advancement of Peace and the Moshe Dayan Center for Middle Eastern and African Studies, both of which maintain collections of books, periodicals, and daily newspapers from Israel, the West Bank, and Arab countries.

There are other institutions in Israel that, though not part of universities, conduct research on the Middle East and maintain collections in Arabic. These include the Givat Haviva Institute for Advanced Studies, which includes the Jewish-Arab Center for Peace that houses an information center includes several dozen items in the field of Middle East studies, including files of newspaper articles published in Israel and various Arab countries, etc. Use of this collection, which offers items in Arabic as well as Hebrew and English, is open to all, but it is used mostly by lecturers, doctoral candidates, college students and high school students working on term papers, including many students from the nearby settlements of Wadi Ara.

Public libraries

During the Mandatory period there were no public libraries for Arabs. Until Israeli educational patterns began to influence the Arab sector, religious organizations played an important role in promoting reading and libraries among the literate elite of this sector. The Moslem

Religious Endowment (*waqf*) still maintains two libraries, in Jerusalem and Jaffa. Their collections consist mainly of Moslem religious and legal literature.^[13]

In the Arab sector, too, the Histadrut played an important role during the pre-State era and the two first decades of statehood. The Arab Department of the Histadrut established 47 clubs in villages of the Galilee and central Israel, each containing 500–3000 library items.

After 1948, the Arab libraries were almost exclusively initiated and operated by Jewish authorities, mixed municipalities, the Histadrut, the Prime Minister's Office, the Department of Libraries of the Ministry of Education and Culture, and other Jewish and Arab organizations.^[13]

The development of modern libraries by the Arab community itself began in the 1970s. This reflected social, political, and educational changes that encouraged the creation of library services in the Arab and Druze sectors. During the 1960s, the Ministry of Interior encouraged the development of municipal self-rule in Arab communities and they began to change. A vast improvement in Israeli communication and transportation systems gave Arab villages access to neighboring urban centers. The combination of high population growth and high unemployment impelled the younger generation to seek employment outside the villages. There was also a growth of light industry and commerce in the villages, in addition to agriculture. Young people went to the universities, and new political power centers began to develop in the villages.

Today, there are 56 independent public libraries in the Arab settlements, 12 libraries that are branches of regional libraries and 5 libraries in mixed settlements. Seventeen Arab towns still do not have libraries. About one-third of the libraries in the Arab sector are located in schools and serve as combined libraries. Indeed, most of the library users in the Arab sector are children and teenagers.

School libraries

Before the British Mandate, there were only a few Arab schools in Eretz Yisrael, supervised by the Turkish Ministry of Education. The British authorities regarded the educational advancement of the Arabs in Eretz Yisrael as an important goal. The public school system was designed mainly for the Moslems, while Christians had missionary schools. The British Mandate's efforts, however, lagged behind the Arab population's growth rate, so that many children still received no education.^[14]

The Compulsory Education Act of 1949 obligated parents to enroll children in school and led to a great improvement in the Arab sector's educational level. In Israel today, there are 417 Arab elementary schools and 202 Arab high schools. Recent years have seen an impressive growth in the number of school libraries in the Arab sector, reflecting the encouragement of increased awareness among the school administrators, especially in the Druze sector. At present, 70% of the elementary schools

have a library and 84% of the high schools. Their collections are smaller than those in the Jewish sector because most Arab libraries were established more recently and have not yet acquired a large stock of books. In addition, they tend to limit their collections to material directly related to the curriculum and do not purchase many fiction books. Moreover, it is difficult to obtain material in Arabic, since it must be ordered from foreign countries. Most is ordered from Jordan (this is also affected by the political situation in the region). Most of the collections in these libraries are in Arabic (71–83%), with only a small proportion in Hebrew.

Professional Education

Until the first school of librarianship was established in Israel in 1956, an Israeli could only become a professional librarian by going to Europe or the United States for training. Under the directorship of Shmuel Hugo Bergmann (1920–1935), the National Library sent workers abroad for training and sometimes employed immigrant librarians who had been trained in their home countries. During 1936–1947, the library profession came to be regarded differently. Fewer people went abroad for training, instead receiving short courses at the workplace as well as on-the-job training.^[15]

In 1956, the first library school was set up as an academic department at the Hebrew University of Jerusalem, the School of Library, Archive and Information Studies, which was closed 3 years ago.

In 1973, the Department of Library and Information Studies was inaugurated at the University of Haifa, where training courses had been provided since 1971. Today this is a small department that offers a postgraduate diploma as well as a librarianship track within the framework of a general B.A.

The following year (1974), Bar-Ilan University opened a department of librarianship, known since 1999 as the Department of Information Science, which has become the largest department in Israel, offering B.A., M.A., and Ph.D., degrees. The areas of specialization it offers are

For the M.A., degree: Organizational Information Services and Knowledge Management; Information Technology; Information Specialization in Cultural and Educational Institutions; and Social Information.

B.A.: Web Technologies; Information studies.

In addition, there are three teachers' colleges that offer nonacademic programs in Librarianship and Information Studies: Beit Berl College (Kfar Saba), Oranim College (Haifa), and David Yellin College (Jerusalem).

There are currently two relevant professional organizations: the Organization of Israeli Librarians was set up in 1952, and its members are mostly librarians of public and school libraries. The Association of Special Libraries and Information Centers in Israel (ASMI) was founded in 1966, and mainly encompasses academic libraries, special

libraries, and information centers. These two professional organizations have decided to merge into one organization and the merger will occur during 2009.

MUSEUMS

Historical Perspective

In Israel today, there are approximately 200 museums involved in the collection and display of art-objects in a wide range of cultural areas: archaeology, history and heritage, art, anthropology, folklore, and Judaica, as well as nature, science, and technology.

The first museums were established under the Ottoman regime. Between 1848, when the first museum was opened in Jerusalem, and 1917, 30 museums were opened in Eretz Yisrael. Most of the museums and collections established in the late Ottoman period were located in either monasteries and churches or schools and research institutes.

The establishment of the museums was influenced by eighteenth century Europeans' growing interest in Middle Eastern archaeology and the settlement of European subjects in Eretz Yisrael and the opening of foreign consulates, which opened educational and cultural institutions. These institutions began to collect archaeological findings and set up museums, although most were not open to the general public.

Meanwhile, the national movements in Europe, including the awakening of the Zionist movement, led to the establishment of Jewish museums in Europe and the United States. Although these expressed the desire to be integrated into the general community,^[16] they also led to recognition of the importance of Jewish culture and efforts to establish national museums in Eretz Yisrael.^[17]

In this spirit, Yosef Hazanovitz proposed establishing a Jewish national library, including a museum and, in 1895, he began collecting portraits of Jewish personalities.

In 1906, the *Bezalel National Museum* was established by Boris Shatz, as part of the Bezalel School of Art that also he founded, and began to collect works by Jewish artists, archaeological relics and local ethnographical artifacts of Jews from Middle Eastern countries. The 1930s marked a milestone in the development of museums, as result of German Jews' arrival in Eretz Yisrael, bringing with them artistic trends and collections that were not present previously. During that period, works by Jewish artists, Dutch paintings from the seventeenth century, and French paintings from the nineteenth and twentieth centuries were acquired and the museum collection of graphic arts was started. After World War II, it became a repository for many art objects belonging to people who had been killed during the war. These collections formed the foundation for the collections of the Israel Museum, which was founded in 1965.

The 1970s and 1980s were a vital period of growth during which new museums of many types were established.^[18] During this period, more than 80 heritage museums and sites were established in *moshavot* (rural towns) and *kibbutzim* throughout the country, to commemorate the nation-building, pre-State era.^[19] Many of them were established through local initiative and later gained public recognition and support.^[20,21] This trend continued into the 1990s, when museums became progressively more interactive and began to rely less on collections of objects.

The interactive trend is evident in both science museums, such as Bloomfield Science Museum in Jerusalem, and historical museum, such as those in Ein Shemer and Yifat. In addition, art museums that are also based less on a collection and more on changing exhibits of contemporary art were founded in Herzliya, Tefen, and other places.

Museums in Jerusalem

A large concentration of museums is located in Jerusalem. Some of them were established during the Mandatory period (1917–1948), some in the period after the establishment of the State in 1948 and the rest in the 1970s.

During the British Mandate, the following, mostly archeological, museums were established or refurbished: *Greek Orthodox Patriarchate Museum* in the Old City of Jerusalem; *The Museum for Islamic Art* on the Temple Mount in the Old City (1923), which is dedicated to Islamic artistic traditions and craftsmanship and the *Franciscan Biblical Museum*, on the Via Dolorosa in the Old City (1902) which houses archeological artifacts that were excavated by Franciscan archeologists.

The Rockefeller Museum was founded outside of the Old City walls in 1938, with a donation from John D. Rockefeller, Jr. It was designed by the British architect Austen Harrison, who combined concepts of Western architecture with Eastern influences. The museum still exists and is now managed by the Israel Museum. Its archeological displays are arranged chronologically; most were unearthed during Mandatory period excavations, including those at Megiddo, Samaria, Beit Shean, Lachish, Jericho, Ha'i, Tel Beit Marsis, Beit Shemesh, and Gezer.

The largest and most important museum in Israel, *The Israel Museum, Jerusalem* was dedicated in 1965. The museum, which is currently (2009) undergoing extensive renovations, has important collections in the fields of archaeology, ethnography, and Judaica, in addition to Israeli and world art. The archeological displays are arranged chronologically, beginning with the pre-historic era and continuing until medieval times. It includes a hall display of the cultures of neighboring countries and the religion and ritual of the Biblical world.

The Judaica and Jewish Ethnography Wing preserves Jewish ritual objects from Jewish communities around the

world, including two synagogues, one from Italy (seventeenth century) and one from Germany (eighteenth century) that were moved to the museum in their entirety. The museum's Judaica collection is one of the largest in the world and it includes important manuscripts, including the Rothschild Miscellany, the Birds Head Haggadah, and the Cassuto Pentateuch.

A separate building, The Shrine of the Book, houses the Dead Sea Scrolls, which were accidentally discovered in a cave at Qumran (near the Dead Sea) in 1947, and were written by the Essenes during the Second Temple period (second century B.C.E. to the first century C.E.) (see Figs. 5 and 6).

It is interesting to note that other than the Israel Museum's Judaica collection and several small collections in small museums (the Ein Harod Museum of Art and the Italian Synagogue in Jerusalem), most Judaica collections are located outside of Israel, in hundreds of Jewish museums around the world.^[20]

Since the 1970s, Jerusalem is again seeing a period of growth and the construction of new museums. *Tower of David—Museum of the History of Jerusalem*, at the Jaffa Gate to the Old City, presents the story of Jerusalem throughout the 4000 years of its history and the central events of each period, with emphasis on the city's importance to the three major monotheistic religions. It is

Fig. 5 The Shrine of the Book, Israel Museum.

Fig. 6 The Shrine of the Book, Israel Museum.
Source: The Israel Museum.

housed in the Citadel and includes carefully tended, internal archaeological garden.

The *L. A. Mayer Museum* for Islamic Art was opened in 1974 and consists of nine galleries, staged in chronological order, displaying the beliefs and art of Islamic civilization. *The Bible Lands Museum*, Jerusalem, (1992) focuses on biblical history through ancient Near Eastern art, from the dawn of civilization through the early Christian era. The museum illustrates the culture of all the people mentioned in the Bible from Egypt eastward, across the Fertile Crescent to Afghanistan, and from Nubia, north to the Caucasian mountains.

Art Museums

In addition to the art collection of the Israel Museum, there are other art museums and many small galleries. The most prominent art museum is the *Tel Aviv Museum* that was founded in 1932 at the initiative of the city's mayor at the time. Meir Dizengoff, who acted to collect outstanding works by Jewish and non-Jewish artists. The museum's Israeli and international collection incorporates a wide range of the paintings, sculptures, drawings, and prints from the impressionist, postimpressionist, modern and contemporary periods. The collection of Israeli artists includes a representative cross-section from the earliest days of Israeli art up to the works of today's current artists. The museum's changing exhibits feature both group and individual shows of Israeli and international artists.

Other art museums include: *The Haim Attar Museum of Art Ein Harod*, which is one of the oldest and largest museums in an agricultural settlement, founded in 1938. The museum building is an architectonic creation that is adapted to the conditions of the local natural lighting and blends into its surroundings. The collections are representative of Israeli art, with emphasis on artists from the

Kibbutz Movement, and Jewish folk art from many Jewish ethnic groups.

The *Haifa Art Museum* was founded in 1951 and primarily deals with Israeli art. *The Museum of Israeli Art* in Ramat Gan was founded in 1987 and is located in a former industrial building that was converted into a museum while preserving its former character. The display is based on changing exhibitions devoted solely to Israeli art of many genres, painting, sculpture, photography, cinema, design, and graphic arts. There is a sculpture garden next to the museum.

In addition to the many galleries, there are also museums that are dedicated to the work of a single artists, for example the *Nachum Gutman Art Museum*; the *Manne Katz Museum*, Haifa; the *Janco-Dada Museum*, Ein Hod devoted to the works of Marcel Janco; and the *Rubin Museum* located in the former Tel Aviv home of painter Reuven Rubin, one of Israel's pioneering modern artists, whose paintings give expression to the life and landscape of Israel.

Archaeological Museums

Many museums in Israel are devoted to local archaeology and most of them focus on findings from an adjacent excavation site. One example is the recently opened *Masada Museum* that displays findings from the rebellion against Rome and the fall of Masada.

Other Israeli museums feature broad archaeological collections. In addition to the *Israel Museum* and the *Rockefeller Museum* (see above), there is the *Eretz Yisrael Museum* with more than 100,000 artifacts and the *Museum of Prehistory of the Hula Valley* at Kibbutz Maayan Baruch in the Upper Galilee with a large collection of more than 120,000 prehistorical findings and ethnographical exhibits from around the world, which illustrate the lifestyle of early humankind.

There are also many artifacts in the collections of small museums in smaller towns throughout the country.

Historical Museums

Throughout Israel there are many historical museums devoted to telling local stories of the people, settlements and organizations which played a role in settling the land and establishing the State.

Many museums concerned with the history of Jewish settlement in Eretz Yisrael are found around the country, some located in the historical buildings where the activities represented actually occurred. In these museums, the emphasis is on the settlement's nascent period, as expressed in a historical collection of documents, photographs, and artifacts from the local material culture including agricultural implements, clothing, and toys. *The Tower and Stockade Museum* at Kibbutz Hanita in the Galilee displays not only to the history of the kibbutz but

also the Zionist enterprise of the tower and stockade (*homa u'migdal*) settlements.

The largest historical museums are *Rishon Lezion History Museum* and *The K'han Museum* in Hadera, which has the largest collection of artifacts from the history of early Zionist settlement. Located in an agricultural building from the Ottoman period, the K'han Museum houses archival documents as well as objects, household utensils, furniture clothing, and decorative objects, as well as agricultural implements and medical instruments from different communities. Many cities, towns, and rural settlements have "Founders Rooms."

The Ministry of Defense Museums' Unit brings together a dozen museums that have a joint collection of many thousand artifacts representing the history of the Jewish defense forces in Eretz Yisrael and their development from the beginning of the *Hibbat Zion* movement (1880s) through the modern military development of the Israel Defense Forces. The Defense Ministry museums include *Beit Hashomer*, Kfar Giladi; *Beit Hagedudim*, Avihail; *Hapalmach Museum*, Hagana Museum, *Ha'etzel Museum*, and *Lechi Museum* in Tel Aviv; and the *Clandestine Immigration and Naval Museum* in Haifa.

The unique *Herzl Museum* in Jerusalem offers information about Theodor Herzl and his Zionist vision for the State of Israel.

Since Israel is a country that has absorbed immigrants from many countries, museums have been established to tell the story of these different communities. Examples include the *Babylonian Jewry Heritage Center* in Or Yehuda, the *Rabbi Shalom Shabazi Yemenite Jewish Heritage House* in Rosh Ha'ayin, and the *Memorial Museum of Hungarian Speaking Jewry* in Safed.

Holocaust heritage museums

Several museums have been established in Israel to document the memory and terrifying stories of the Holocaust perpetrated by the Nazis against the Jews during World War II. This category includes the *Yad Vashem Museum*, *The Ghetto Fighters' House—Itzhak Katzenelson Holocaust and Jewish Resistance Heritage Museum*, *Yad Mordechai Museum*, *Massuah Interactive Educational Museum* at Kibbutz Tel Yitzhak, and the *Diaspora Museum*.

Yad Vashem Museum in Jerusalem was established in 1953, in accordance with the provisions of Holocaust and Heroes' Remembrance—Yad Vashem Law. The Museum now resides in new building that was designed by architect Moshe Safdie and includes an impressive display using many different types of media to depict events during the Holocaust in chronological order, with emphasis placed on human-personal stories. Yad Vashem houses a documentary archive of the Holocaust (see the section on Archives). The museum includes the Hall of Names where the names of the individual victims are stored as well as

other unique memorial sites: the Valley of the Communities, the Children's Memorial, and The Hall of Remembrance.

Ghetto Fighters' House—Itzhak Katzenelson Jewish Resistance Heritage Museum at Kibbutz Lohamei Hagetaot in the Western Galilee was founded in 1949 by a community of Holocaust survivors, members of the Jewish underground in the ghettos of Poland and veteran of partisan units. The exhibitions include the background of the Jewish communities before the Holocaust and the Jewish resistance during the Holocaust.

Beit Hatefutsoth—The Nachum Goldman Museum of Jewish Diaspora in Tel Aviv was established in 1978 to convey the story of the Jewish people from the time of their expulsion from the Eretz Yisrael 2500 years ago to the present. The museum is unique because the exhibits are arranged by topic, rather than chronologically.

Science and Nature Museums

Israel has two relatively small science museums: one in Haifa, the *National Museum of Science, Technology and Space*, founded in 1984, and the *Bloomfield Science Museum* in Jerusalem. These museums emphasize understanding scientific principles rather than collections.

There are several small museums devoted to nature, agricultural, and local history at locations throughout Israel, including *Beit Ussishkin Nature Museum* at Kibbutz Dan in the Upper Galilee and *Yigal Alon Museum of Man in the Galilee* which focuses on the landscape of the Galilee during different historical periods. Among its exhibits is an ancient boat, dated from the first century C. E., known as the "Jesus Boat," which was discovered on the shores of the Sea of Galilee in 1986.

The Arab Sector

The Arab sector still lacks significant museums, despite several attempts that have been made, some in cooperation with the Ministry of Culture's Museum Department, to establish some. These attempts have been made in Uhm El-Fahm, Shefaram and the Druze Museum in Jat-Yanuch. There are also small, private exhibitions, which are not recognized as museums, in Ussifiya, Daliyat-El-Carmel, Shibli, and elsewhere.

Official Recognition of Museums

In Israel today, there are approximately 200 museum-like institutions but only 53 are officially recognized according to the Museums Law of 1983, which established a procedure for official recognition of museums. Recognition of a museum entitles it to financial support from the State, via the Ministry of Culture. A recognized museum is required to meet professional standards regarding the employment of professional staff members, proper preservation of

displays, record keeping, descriptive and photographic records of the exhibits, and making information about them available to the public. This law states that a museum's management is to be granted freedom of action, as long as it complies with its bylaws and budget.

The Ministry of Culture, through its Museums Department, works to ensure that recognized museums comply with the law and regulations, guides museums through the process of receiving recognition and advises museums in the process of being established. By law, a 21-member public board of directors advises the heads of ministry's Museum Department on matters of policy and budgetary allocations to recognized museums. In addition, some museums receive funding from municipalities. The remainder of the budget is covered by independent income and contributions from the private sector.

In 2005, there were 3,110,393 visits to the 53 budgeted museums. Of these 21% were guided tours for pupils. In addition, 23,299 teachers took in-service training courses given by museums.^[22]

Professional Education

Two Israeli universities have diploma programs in Museology. At Haifa University the program is part of humanities faculty and meets 2 days/week for 1 year while the Tel Aviv University program is in the arts faculty and meets 1 day/week for 2 years.

ARCHIVES

The Archives Law and the State Archives

The beginning of legislation regarding archival material dates to the period of the British Mandate and dealt with keeping court files (1935). After the establishment of the State (1948), the Antiquities Ordinance (1935) protected books and manuscripts produced before 1700. The preservation of newer materials was covered by the Archives Law in 1955. This law establishes arrangements for all archival material existing in Israel, with particular emphasis on official material (from government ministries, the Knesset, the judiciary, government corporations, and local authorities). According to this law, the system is headed by the State Archivist, who is appointed by the Prime Minister and manages the Israel State Archives, established in 1949. The State Archivist is responsible for implementation of the law. One function of the State Archive is to receive for deposit all archival material dating from before the establishment of the State, from government institutions and local authorities that have ceased to exist and from all government institutions and local authorities that are inactive and which have value for permanent preservation. An additional function, related to the first, is supervision of the archival arrangements in

state institutions and local authorities. This is the source of the legal requirement that none of the aforementioned institutions may dispose any material, except in accordance with the guidelines and regulations. Any person may use material deposited in the State Archives, dependent on limitations related to its type and period of closure. In order to ensure the preservation of archival material in the possession of individuals, which has value for the study of the past, the people, the state, or society, the State Archivist manages a register, based on the declaration given by the person who owns or possesses it. In order to protect the individual's rights, the Archivist is not permitted to read this material without the agreement of the person who owns or possesses it. The law permits taking archival material out of the country only if the Archivist is permitted to read and copy it or if he waives this requirement.^[23,24]

Regulations for the practical implementation of the Archives Law were added later: regulations regarding transferring archival material to storage; regulations regarding the management of public archives (see below); regulations regarding use of archival material deposited in the archive, including those with limited access rights; regulations usage fees and regarding the disposal of archival material by state institutions and local authorities.

The State Archives fulfills the functions enumerated in the law using a structure that includes the following departments: Research and Public Services, Supervision and Training Unit, Preservation and Restoration Laboratory, Audio-visual Department, Information and Registration Department, Computerization Department, Division for State Documents, Memorials and Official Publications and Repository. The archival material deposited in the National Archive includes 40,000 linear meters (43,744 linear yards) of shelves with 3,750,000 files; 1500 movies and videos; 150,000 photographs and negatives, and 10,000 audio recordings. One million documents have been digitalized and half of them can be accessed via the Internet. The aforementioned audiovisual material has also been digitalized. There is a computerized registry of all paper materials on the record group and subrecord group levels and of 70% on the file level. A portion of this computerized system is accessible to readers in the reading room. In 2004, the State Archives adopted the International Standard for Records Management (ISO 15489) and is preparing to develop a comprehensive program for managing and preserving electronic records. The program is being adapted to Israel's unique needs. (<http://www.archives.gov.il/ArchiveGov> Information received from Assaf Tractinsky, head of the Information and Records Department of the State Archives.)

Branch Archives

There are also archives that are branches of the State Archives. The most important of these is the *I.D.F.* &

Defense Establishment Archives, which was established in 1948 and includes, in addition to materials from these institutions, documentation on the underground organizations that preceded the establishment of the State, the Jewish volunteers who fought in the world wars and a collection on Jewish soldiers beginning in the nineteenth century. This archive includes approximately 9 million files; audiovisual documentation (approximately 10,000 videos recordings, approximately 65,000 audio recordings, and approximately 500,000 photographs and negatives), maps, drawings, and digital documentation. Approximately 5 million pages of declassified, scanned documents are accessible to readers in accordance with the Archives Law, 50 years after their creation. Since security, the military, and society in Israel are closely intertwined, information related to the fields of the education, culture, medicine, economics, religion, and the law can be found in this archive. (Information received from Mihal Tzur, Manager, *I.D.F. & Defense Establishment Archives*.)

Other branch archives of the National Archives are the *Ben Gurion Heritage Institute Archives* at Sde Boker, *The Yitzhak Rabin Center for Israeli Studies Archives*, and the *Menahem Begin Heritage Foundation Archives*.^[25,26]

Municipal Archives

Although the Archives Law allows the depositing the archives of local authorities in the State Archives (see above), the State Archivist's policy was to develop special local archives in the older cities and towns, in order to develop local heritage. Not only administrative materials from the local authorities are deposited in these archives but also the archives of institutions, organizations, economic corporations, and individuals who were active there. The archives also house photographs, city publications, announcements, posters, and maps. Local authorities maintain 54 historical archives with the most important being in the three largest cities.^[27]

The Jerusalem City Archives was established in 1963. The earliest material in the archive dates from the mid-eighteenth century and belongs to the Sephardic Community Committee record group. The municipality, itself, was established only in 1863 by the Ottoman authorities. There is a small amount of material remaining from that period, beginning from 1892 (records of city council decisions). From the British period (1917–1948), there remains continuous documentation of the city council and various municipal departments. This sequence continues after the establishment of the State of Israel, when Jerusalem became its capital. From the years following 1948, the archive also includes documentation of the city's mayors, deputy mayors, councilors, the bureaus of the city managers and their deputies, and various advisors to the mayor (a total of 502 subrecord groups and series). The archive also houses 53 record groups for various institutions that

have closed such as the Jerusalem Community Committee and the City Committee; 15 archives of neighborhood committees and 89 from schools that have ceased to exist. In addition, there are 93 economic archives and personal archives of professionals (architects, engineers, accountants), educators, artists, authors, and rabbis. The total size of the historical archive is 4000 linear meters (4374 linear yards) of shelves. There is a computerized archival management system. The municipal archive is also responsible for the city's records management. (Information received from Michael Mahler manager of the Jerusalem City Archives and Menahem Levin, the former manager of the city archive.)

The Municipal Archives Tel-Aviv—Yafo houses material beginning with the establishment of the Ahuzat Bayit Association in the 1906 and minutes of the Yafo Community Committee from 1896 to 1898. The historical archive was opened to the public in 1971. It was preceded by the municipal records center. Today there are two branches of the municipal archive department. There are 38 record groups in the archive for city departments, archives of the cultural, sports, and commercial organizations, etc., including the files of 28 mayors, deputy mayors, members of the city management and councilors and 11 record groups of personal archives and private documents. Furthermore, it houses collections of municipal publications, posters, and maps. The total shelf length is 1500 linear meters (1640 linear yards). There is a computerized system for recording and retrieving information. The photographic collection is digitalized.^[28] (Information received from Ziona Raz, manager of the The Municipal Archives Tel-Aviv—Yafo.)

The Haifa City Archives was founded in 1977 and includes 2000 linear meters (2187 linear yards) of shelves. The earliest material is from the Hebrew Community Committee and neighborhood committees in 1920s, with city council records starting in 1926. Most of the material comes from the municipality and its institutions but there are also 45 private archives from individual and institutions that are valuable for the history of the city. The archive is also responsible for managing municipal records. (Information received from Mihal Hankin, manager of the Haifa City Archives.)

Public Archives

The Archives Law recognizes “public archives,” which are defined as “an archive that is owned or managed by a non-profit organization and recognized by the government as a ‘public archive,’ in an announcement published in the Official Record.”^[29] There are 17 public archives that have been recognized on the basis of this definition. (Additional information on the most important may be found below.) According to the Regulations regarding Arrangements for Managing Public Archives, a public archive can be recognized if it has bylaws that define its

purposes and missions; the conditions for permitting study and use of the material and if the archive has the organizational and financial necessary to develop its activity. The managers of public archives must submit an annual report to the State Archivist. The public archive category includes historical, administrative, and documentary archives, the archives of political movements and memorial organizations. Each of the public archives has a library to supplement the archival collection. In addition to books on the subject, they also include collections of newspapers and periodicals, which contain some unique and rare copies.^[30]

The Central Archives for the History of the Jewish People, Jerusalem (CAHJP) was founded in 1939 by the Historical Society of Israel for the purpose of reconstructing an unbroken chain of historical documentation that reflects the collective past of the Jewish people. It was reorganized in 1969. The collection includes 6000 linear meters (6561 linear yards) of shelf space of material gathered from 1600 archives of communities, organizations, and individuals; 9 million frames of microfilmed documents; 2000 lists of documents and files concerning Jews held by in other archives; 12,000 photographs; 8000 publications; 1 million newspaper clippings; and 12,000 books and publications on Jewish history. The archive includes materials from the entire Jewish Diaspora.^[31]

The Central Zionist Archives (CZA) (Fig. 7) was established in Berlin in 1919 and serves as an historical archive of the World Zionist Organization, the Jewish Agency, the National Funds, and the World Jewish Congress, documenting the growth of the Zionist movement around the world, from its beginnings in the 1880s. When the Nazi rose to power in 1933, the archive was moved to Jerusalem. Since then it has acquired the function of the being the historical archive of the new Jewish settlement in Eretz Yisrael. In parallel, it was decided to

systematically collect the personal archives of leaders of the Zionist movement and the pre-State Jewish settlements. It also continued to collect books, periodicals, and photographs. When the State was established in 1948, many files from the Jewish Agency and National Committee, whose functions were transferred to ministries of the new government, were deposited in the CZA. The rapid growth of the collections and the poor storage conditions led to the decision to build a special building for the CZA, the first of its kind in Israel. It was dedicated in 1987. In the 1990s, CZA undertook computerize its collections and a massive effort began to enter the titles of thousands of files and other collections into the computer. Since then the CZA has scanned over 14 million documents, 350,000 photographs, 90,000 maps and settlement plans, 26,000 posters, and 1,200,000 cards containing genealogical information, and 1600 sound recording. The CZA is currently adapting a Web-based document management system to manage its data- and image-base with the intention of making its records available to the wider public. The archive houses 10,000 linear meters (10,936 linear yards) of archival material divided into approximately 400 organizational record groups and 1200 personal archives. There are 500,000 photographs, 50,000 maps and plans, more than 18,000 posters and flyers, and 13,000 newspapers and periodicals. In cooperation with the Hebrew University, the archive manages the *Steven Spielberg Jewish Film Archive* that includes more than 3000 film and video titles. In addition to the customary services to scholars and other interested people, it is notable that CZA has developed a genealogy department and educational activities.^[32,33] (Information received from Rochalle Rubinstein, deputy manager of the CZA.)

The Yad Vashem Archives was established in 1953, as part of the Holocaust Martyrs' and Heroes' Remembrance Authority. Its purpose to document the history of the

Jewish people during the Holocaust period, preserving the life stories and memories of each one of the 6 million who perished and transmitting the heritage of the Holocaust to coming generations. Gathering materials for the archive began in 1946. It is the world's largest collection of materials related to the Holocaust, with 62 million documents, more than 268,000 photographs, tens of thousands of testimonies dictated, recorded or videotaped by Holocaust survivors in Israel and abroad. There are also several thousand original film titles including raw materials, cinema newsreels, amateur movies, propaganda films, and more. The Hall of Names is designed to remember the Jewish victims in the Holocaust as human beings and individuals. It currently includes more than 3 million names, gathered from more than 2 million Pages of Testimony and other lists of victims. Yad Vashem has scanned all of the Pages of Testimony and photographs, and has computerized systems to locate and retrieve information.^[34]

The Labor Archives was founded in 1932 by the Histadrut. Since 1982, it has been part of the *Pinhas Lavon Institute for Labor Research*. It was founded for the purpose of gathering archival material from all Histadrut institutions and from individuals and organizations that were active in Eretz Yisrael from the beginning of the twentieth century. Its record groups include ones for material originating in the Histadrut, its institutions, organizations, and departments; political organizations related to the labor movement; youth movements from the labor sector; the Labor Movement overseas; archives of the Workers Councils and of individuals, for a total of 170,000 files. There are also departments of oral testimony, photographs (approximately 50,000), in addition to a collection of approximately 10,000 glass negatives taken by the photographer Avraham Suskin and a collection of photographs (approximately 500,000) from the newspaper *Davar*, videos, and posters.^[35] (Information received from Alexandra Tumarinson, manager of the Labor Archives.)

The Jabotinsky Institute in Israel was established in 1933 for the purpose of gathering documents, publications, and photographs related to Ze'ev Jabotinsky and the Revisionist Zionist Movement. The archive holds 366 personal archives of leaders of the Revisionist Movement, including that of Ze'ev Jabotinsky and 188 archives relating to all branches of the movement and its institutions, in Israel and abroad, including the New Zionist Organization (N.Z.O), the Beitar Youth Movement, the National Labor Federation, etc. Additional collections include oral documentation (550 files of testimony and 1000 recordings), approximately 35,000 photographs, 150 films and videos, 300 flags, and several hundred stamps. There is a computerized system to search and retrieve the aforementioned information.^[36] (Information received from Masha Zolotarevsky and Amira Stern, manager of the Archive.)

Kibbutz Movement Archives are a special type of public archive where materials originating in the central institutions of the five movements, each with its own ideology,

of economically and socially collective settlements in Eretz Yisrael and the State of Israel. Several of the movements merged and this process is evident in the organization of their archives: *Yad Tabenkin Archive* at Efal, *The Takam* (United Kibbutz Movement) *Archive* at Hulda and *The Hashomer Hatzair* (Young Gard) *Archive* at Givat Haviva, as distinguished from the *Kibbutz Hadati* (Religious Kibbutz Movement) *Archive* at Kvutzat Yavne.^[37–41] (Information received from Milca Har-Tal, Yad Tabenkin Archive.)

The common denominator of these archives is that, in addition to administrative record groups, they include the archives of the movements' allied youth movements, in Israel and overseas, as well as the relevant political parties, educational institutions, personal archives, publications, and journals. Each of these archives has a computerized archive management system that includes work stations for employees and the public. Most of the collections are computerized.

The archive that has gathered the largest collection is that of Yad Tabenkin, because of its position in the merged movement. Founded in 1957 as the archive of *Hakibbutz Hameuhad* ("The United Kibbutz," 1927–1980), it was housed at Ein Harod. In 1975, it was moved to Hakibbutz Hameuhad's seminar center in Efal, where it is part of an educational-research complex. With merger of Hakibbutz Hameuhad and *Ihud HaKvutzot veHaKibbutzim* (Union of the Kvutzot and Kibbutzim, see below) and the establishment of the United Kibbutz Movement in 1980, material generated in the new movement was divided between Yad Tabenkin and the United Kibbutz Movement Archive at Hulda (see below). This arrangement continued until 2000, when *Hakibbutz Ha'artzi* (The National Kibbutz) joined the United Kibbutz Movement to form The Kibbutz Movement. Since then, all material created by the new organization has been deposited at Yad Tabenkin, which has 543 record groups and subrecord groups, 240 personal archives, and 2500 linear meters (2734 linear yards) of files. In addition, there are approximately 100,000 photographs, 1600 posters, and 2000 audio recordings. The archive is in the process of digitalizing its documents and photographs. *The Takam Archive* at Hulda was founded in 1963 and incorporated the archives of *Hever Hakvutzot* ("League of Kvutzot," 1925–1951) and the *Ihud HaKvutzot veHaKibbutzim* (1951–1980). Until 2000, materials from some departments of the United Kibbutz Movement were deposited here but since then, no new material has been added. The archive has 919 linear meters (1005 linear yards) of shelf space.

The Hashomer Hatzair Archive at Givat Haviva was founded in 1937 at Kibbutz Merhavia and belongs to *Hakibbutz Ha'artzi* of Hashomer Hatzair. In 1982, it was transferred to Givat Haviva and became part of the movement's *Yad Ya'ari* ideological and documentation center. It includes 2680 linear meters (2930 linear yards)

of shelf with approximately 200,000 photographs, approximately 1000 posters, 3220 audio and/or video recordings and the approximately 600 flags and other museum-type exhibits.

The Kibbutz Hadati Archive was founded in the 1976 and includes administrative material from the movement dating from 1931 and other materials related to religious Zionism, going back to 1917. In addition, to material from the movement offices, other affiliated institutions deposit material in this archive, which houses 7000 administrative files, 3200 files of collections, 16,800 photographs, and approximately 1500 audiovisual items.

The Jewish National and University Library (see above) includes five archival departments: The *Albert Einstein Archives*, which includes scientific, public, and personal material that was transferred from Princeton to the National Library in 1982 (also includes rare material on Sir Isaac Newton). The *Manuscripts and Archives Department* was founded in 1968 (previously, from 1923 to 1968, archives were cataloged as Judaica). In 2006, the manuscripts were separated from the archive, which became the Archives Department, which incorporates 450 personal archives of intellectual leaders of the Jewish world, including Martin Buber, S.Y. Agnon, and Else Lasker-Schüler. It also houses archives of living people including author A.B. Yehoshua and poet Haim Gouri, plus 40 archives from institutions and settlements and 300 collections of various types. (http://www.jnul.huji.ac.il/eng/col_special.html, Information received from Rachel Mashrati, Archives Department, The Jewish National and University Library.)

The Music Department began operations in the 1964 and its importance increased in 2000 when the law requiring mandatory deposit of publications was expanded to include audiovisual materials. It is divided into two sections: the department itself and the National Sound Archives. The Department houses collections of notated Jewish music from the sixteenth century to the current day; 225 personal archives of Jewish and Israeli composers from the last century; 25 archives from musical institutions, and other relevant research materials. Recordings of Jewish music of all types and of other ethnic groups in Eretz Yisrael (Arab Moslems, Christian communities, Circassians, and Druze) are deposited in the National Sound Archives. The collection began in the 1920s and includes 30,000 hr of recordings. In addition, there are 10,000 hr of the ethnographic documentation, 15,000 hr of commercial recordings, and 5000 that were deposited by the Israel Broadcast Authority. (Information received from Dr. Gila Flam, manager of the Music Department and National Sound Archives, The Jewish National and University Library)

The newest archive is *Israeli Internet Sites Archive*, an experimental attempt to preserve copies of Internet sites in their entirety.

Archival Science as a Discipline and Profession

Until the middle of the twentieth century, Israeli archival science inherited the traditions that the first archivists brought from Germany and was also strongly influenced by the British (H. Jenkinson) and American (T. Shellenberg) schools, which were accepted during that period. Only in the late twentieth century and the early twenty-first century were echoes of new streams of thought, such as the social value of archives and the influence of the macroappraisal theory and practice. Despite the existence of programs for educating archivists and the work of certified licensed archivists, the law does not require someone to have professional certification, in order to manage an archive. Either an academic diploma or 5 years of experience is considered sufficient.

Educating Archivists

During the 1950s, archivists were educated through on-the-job training. In 1960–1961, the Hebrew University held the first course for certified archivists. Beginning in the early 1970s, these courses became part of the Hebrew University School of Library, Archive and Information Studies. Until its closure in 2003, this was the only institution in the country that granted a diploma or master's degree in the profession.

The Information Science Department of Bar-Ilan University teaches several individual courses that deal with archival science.

Parallel to the university programs, the National Archives, the civil service commissioner, municipalities, the Israel Archivists Association, and the Kibbutz Movement also hold courses for archivists and records managers. Each course is designed for different sector working in the field of archives. These courses train people on a practical level. In the 1990s, at the initiative of the State Archives and the Israel Archivists Association, three colleges: Max Stern Academic College of Emek Yezreel, Beit Berl Academic College, and David Yellin College of Education began to offer programs at the bachelor's degree level toward a certified archivists diploma.^[42]

PROFESSIONAL ASSOCIATIONS

The first attempt to organize an archives association was in 1951 but the Israel Archive Association (IAA) was not founded until 1956. Its members included both representatives of archives and individual members but only institutional members were permitted to sit on the Board of Directors until 1982 when permission was given for individual members to join the board. This trend gained strength as the number of individual members grew and in 1993, IAA became an organization consisting solely of individual members with elected institutions and the

current name, Israel Archivists Association, was adopted. Throughout its existence, the Association's primary activity consisted of professional in-service training courses on various levels and professional ranking of its members. It is a member of the International Council on Archives and members of the IAA have served as officers and committee members of the international organization. The Association sponsors three publications: an annual professional journal *Arkhiyyon, Meida* ("Information") a quarterly review, and *Studies in Archives*, which publishes transcripts of lectures from seminar days. The IAA has an Internet site in Hebrew.^[43] (Updated to 2007 by Zohar Alufi, Chairperson of the Israeli Archives Association.)

ACKNOWLEDGMENTS

We wish to thank the following people who kindly provided us with current information on agencies referred to in this entry:

Victor Ben Naim, Director, Department of Libraries, Ministry of Science, Culture and Sport.

Idit Amihai, Director, Department of Museums, Ministry of Science, Culture and Sport.

Abstract

This entry provides an overview of information services in Japan, with separate sections on libraries, archives, and museums. Libraries and collection of documents have a long history in Japan, based on a fundamental respect for written information and knowledge. Archives in Japan are divided into three main groups: public archives, university archives, and private archives including business archives. The history of modern museums in Japan dates back to the time of the Meiji Restoration. After examining the historical evolution of libraries, archives, and museums, the author discusses current trends and activities such as professional education, professional associations, digitization projects, and cooperative efforts.

GENERAL ORIENTATION

Consisting of over 3000 islands, Japan is an East Asian archipelago located in the north Pacific. It lies to the east of the People's Republic of China, North Korea, South Korea, and Russia. With over 127,704,000 residents, Japan is the 10th most populous country in the world and is a member of the United Nations, G8, and the OECD (Fig. 1).

HISTORICAL INTRODUCTION

It is difficult to say exactly when libraries first appeared in Japan. There must have been some collection of documents even before any library came into existence. In the sixth and seventh centuries A.D., the advent of Buddhism promoted an influx of Chinese classics and the arrival of scholars, as well as the growth of Japanese academic and publishing culture. With this, the importation of documents and the practice of archiving grew to significant proportions. The Bureau of Books and Drawings (*Zushoryo*), a government organization in charge of document storage in the ancient period, can be seen as early as 702, when it appeared in the *Taihoryo* (Taiho Code of Laws) that was promulgated in that year.

In addition to government repositories, it is generally known that, even in the ancient period, a number of institutions made their archival collections open for public

consultation. These included the *Untei* library of Isonokami no Yakatsugu, thought to have existed at the end of the Nara era in the second half of the eighth century AD, and the Kobaiden of Sugawara no Michizane, at the end of the ninth century. Regrettably, neither of these collections has survived. In the medieval period, many repositories were created for temples or by samurai families. These include the Ashikaga School, known for its precious collections that still survive (there are various theories as to the date of its creation, but it was revived in the middle of the fifteenth century) and the *Kanazawa Bunko* repository, established in the mid-thirteenth century (Fig. 2).

Historians suggest that the development of Japan's modern libraries, archives, and museums emerged following the 1868 Meiji Restoration. The first museum was established in 1872, when the institutional system of the Meiji government was consolidated. In the same year, the *Shojakukan* Library was set up inside the Museum (*Hakubutsukan*). Hisanari Machida, the inaugural curator, envisioned a museum with a large-scale library on the model of the British Museum, which he saw while studying in Britain. The main collection of the *Shojakukan* Library consisted of works from the former *Shoheizaka Gakumonsho* school. The Museum and the *Shojakukan* Library were initially under the jurisdiction of the Ministry of Education, which had only been established the previous year. They were subsequently transferred to the Ministry of Home Affairs. Some museums were then transferred to the jurisdiction of the Ministry of

Fig. 1 Map of Japan.
Source: CIA World Factbook.^[1]

Agriculture and Commerce, the Imperial Household Agency, while others were transferred back to the Ministry of Education in 1874.^[2] In the early years of the Meiji era, museums were divided into two types: those connected to the Ministry of Home Affairs, and those connected to the Ministry of Education, respectively. The first of these was initially known as the Imperial Household Museum, which later became the Tokyo National Museum, while the latter was the National Science Museum.

The collections of the *Shojakukan* Library, Japan's first governmental public library, remained under the jurisdiction of the Ministry of Internal Affairs but were moved first to the Asakusa Repository and then to the Cabinet Library. Meanwhile, the Tokyo *Shojakukan* Library, established by the Ministry of Education using the buildings of the former *Shojakukan* Library in Yushima, started to build a new collection from 1875. This then moved to the Imperial Library. After the Second World War, its jurisdiction was transferred from the Ministry of Education to the National Diet (Japan's Parliament), whereupon it became the National Diet Library (NDL). The books from the *Shoheizaka Gakumonsho* school that we find in the NDL today are books that were released to accompany the transfer of stacks during the Meiji years.^[3]

In terms of maintaining public repositories, a "record compiling clerk" was appointed among the administrative officials in the *Dajokan* (Department of State) in 1868. The *Dajokan* system was reformed in August 1871, and a Records Bureau that would "oversee the work of documentary record compilation" was set up in the Main Office of the *Dajokan*. In the following year, 1872, a Records Division and a History Division were set up within the Records Bureau.^[4] This marked the beginning of Japan's documentary administration. After subsequently passing through various different guises (such as the Records Department of the Clerical Bureau in the *Dajokan* and the Records Division of the Cabinet Clerical Bureau), in 1885 it became the Cabinet Records Bureau, and again in 1893 the Records Division of the Cabinet Clerical Office.

Thus, while it would appear that a system for central management of official documents was initially developed, this gradually shifted to a system of decentralized management. In July 1942, the Records Division of the Cabinet Secretariat passed its administrative work to the General Affairs Division of the Cabinet Secretariat, whereupon a document management institution with the word "Records" in its title disappeared from the state bureaucracy. Under the Constitution of Japan, the National Archives of Japan was finally launched in July 1971, having previously been the General Affairs Division of Prime Minister's Agency Secretariat and the General Affairs Division of the Prime Minister's Secretariat.^[5]

The remainder of this entry will provide an introduction to contemporary Japanese libraries, public archives, and museums will be introduced individually.

LIBRARY AND INFORMATION PROFESSIONS, SYSTEMS, AND SERVICES

Legislation Concerning Libraries

The library is called “*toshokan*” in Japanese. The “*Toshokan-rei*” (the Library Decree) was issued for the first of the kind as an Imperial decree in 1899. This law was totally reformed to “*Toshokan-ho*” (the Library Law), enforced in 1950, after WWII. The basis of the new Library Law was the Social Education Law, and thus it stipulated that public libraries be tax-supported, free of charge and required, and the law required librarians adequate to meet the information needs of the community. In addition, the Library Law allows that a library can be established by anyone, not only by public organizations.

Under the Library Law, a public library is defined as a facility established by a municipal government or non-profit foundation. In 2007 there were approximately 3000 public libraries under local governments and 20 libraries under nonprofit foundations. The qualifications to become a professional librarian are regulated by law. Librarians must be college graduates who have taken certain accepted library science courses.

With respect to legislation regarding other kinds of libraries, the National Diet Library is regulated by the National Diet Library Law (enacted in 1948). University libraries are legally based on “*Daigaku Setchi Kijun*” (University Establishment Standards, enacted in 1956), under “*Gakko Kyoiku-ho*” (School Education Law, enacted in 1947). School libraries are based on the School Library Law (enacted in 1953), which is also under the School Education Law.

Copyright Law is another aspect of legislation concerning libraries. The origin of Copyright Law in Japan dates back to 1899, although the law was revised in 1970 and 1978 in response to the advent of new audiovisual materials. It allows libraries to provide photocopy service to a maximum of half of a book if more than 50 years have passed since the author has passed away. Along with the increase in quantity of library services, it is now controversial whether libraries should accept public lending rights in the face of complaints from the viewpoint of protecting authors' rights.

NDL and Information Services

The NDL is the national library belonging to the Diet (Japan's Parliament), established in 1948. As the legal depository library, the library acquires all kinds of materials published in Japan to preserve them for the national cultural heritage. Taking advantage of this library collection, NDL provides various services such as compiling the Japanese National Bibliography, reference service to the members of the Diet, providing a reading room for the public, interlibrary loan, and Internet services to

remote users. In addition, NDL offers a bibliographical database of digital talking books and Braille books and imperative services for visually disabled users. NDL has three facilities: the Tokyo Main Library, the Kansai-kan (a new facility in the Kansai region), and the ILCL (International Library of Children's Literature, also opened in 2002). The Tokyo Main Library comprises the Research and Legislative Reference Bureau, Administrative, Acquisitions, Bibliography, Public Services, Reference and Special Collections Departments, together with the Detached Library in the Diet. The *Toyo Bunko* (Oriental Library) and 26 branch libraries in the executive and judicial agencies also report to the NDL.

The origins of the NDL date back to the Imperial Library, established in 1872 under the Ministry of Education. The Lower House Library and House of Peers Library, established in 1891, were later incorporated, and the three libraries became the NDL during the Occupation era. The NDL was opened to the public in 1948, and later moved to the current Main Building adjacent to the National Diet in 1961. The NDL has 923 staff members, a 2.5-billion yen book budget (FY 2007), and a collection of 8.6 million books and 11 million serials items (FY 2005). The Library has also been acting as the Japanese National Centre for ISSN since 1976 and as the Asia Regional Center for the IFLA Preservation and Conservation since 1989.

The NDL promotes digital library projects as one of its priority areas (Fig. 3). Through the NDL Web site (<http://www.ndl.go.jp>), the following digital services are open to public: 1) Rare Books Image Database; 2) Digital Library from the Meiji era (1868–1912, 1912–1926); 3) Web Archiving Project (WARP) which collects and preserves Web sites and online periodicals on the Internet; and 4) Digital Archive Portal, which provides access to Japanese digital information; and cross database searching is now possible for NDL-OPAC, etc.

Academic and Research Libraries

Japan's first modern university was the University of Tokyo, which was founded in 1877. It became the foundation of the imperial system of higher education in pre-World War II Japan. Some faculty libraries were built in the same year. The UT main library was built in 1892 and rebuilt in 1928 after the Great Kanto Earthquake, with aid of the Rockefeller Foundation and others. In addition to other public universities, private universities, such as Waseda University and Keio University, were officially approved under the University Order, enacted in 1918. After World War II, the higher educational system was dramatically reformed. More and more citizens were able to pursue a higher education, unlike the pre-war situation, when universities existed only for the privileged elite. Today 50% of high school graduates go on to a university or junior college.

Fig. 3 Photo of NDL, Kansai-kan.

During the 1960s and 1970s, a number of universities (mostly private) expanded their enrollment with Japan's rapid economic growth. "*Daigaku Setchi Kijun*" (University Establishment Standards) by the Ministry of Education contributed to maintaining a certain quality among new university libraries. Many more universities built main libraries with open-shelves and free access for graduate students.

University libraries' catalogs were mostly automated and networked in the 1980s. The NACSIS (the National Center for Science Information Systems) was established by the Ministry of Education in 1986 to create the academic information network. The automation of libraries was accelerated by NACSIS, particularly from the perspective of technical services to OPAC preparation. NACSIS was reorganized in 2000 as the NII (National Institute of Informatics). NII provides the following services online for researchers and academic libraries:

1. NII is primarily a research laboratory with more than 80 information science researchers and 60 staff.
2. Webcat (http://webcat.nii.ac.jp/webcat_eng.html) is the online union catalog of the books held nationwide by university libraries. This system is linked to the national interlibrary loan system.
3. The GeNii (NII Scholarly and Academic Information Portal) offers databases in partnership with more than 270 academic associations, including some full-text information.

In terms of legislation, the National University Corporation Law was revised in 2003, and former national universities have now gained corporate status. Since 2004, all universities must be evaluated at least once every 7 years by a quality assurance agency certified by the agency now known as the Ministry of Education, Culture, Sports, Science and Technology (MEXT) (Table 1).

Public Libraries

Public libraries are quite common in Japan, being established in each city (local community with a population over 50,000) and in 50% of all towns and villages. The average public library holds 110,000 books, and lends 200,000 volumes per year. On average, each Japanese citizen borrows about five books in a year from a public library. Public libraries are especially popular with younger people, such as students preparing for college entrance exams, and with children accompanied by mothers who use the children's corner, situated conveniently near the entrance. Bunko, small voluntary libraries for children, usually run by parent groups, are quite popular at the neighborhood level. Meanwhile in larger cities, services providing business information, legal information, and medical information are popular (such as at the Tokyo Metropolitan Central Library or Chiyoda Public Library) (Fig. 4).

Although public library service was quite limited before WWII, the number of public libraries greatly increased during the 1960s and 1970s. *The Management*

Table 1 Statistics of university and junior college libraries (as of 2006).

	Number of libraries	Number of acquired books per year	Number of books borrowed	Number of students
National	297	1,559,000	6,854,000	628,945
Public	122	433,000	1,772,000	127,860
Private	919	4,775,000	19,938,000	2,102,402
Total	1,338	6,767,000	28,564,000	2,859,207
Junior College	256	328,000	1,236,000	202,197

Source: Statistics by JLA.

of *Public Libraries in Medium and Small Libraries*, published in 1963 by the Japan Library Association (JLA), emphasized the importance of services for smaller local libraries. Since then the network of prefectural libraries and small branch community libraries has grown steadily. Following the economic downturn in the 1990s many public libraries have been affected by legislation supporting a Designated Manager System (*Shitei Kanrisha Seido*) or PFI (Private Finance Initiatives). The private sector has become involved in libraries' services and operations. It is thought that the policy has caused a degradation of services, which goes against the spirit of the Library Law, however more and more local governments have adopted the policy as the central government has cut its budget for public facilities (Table 2).

School Libraries

The Japanese School Library Law, enacted in 1953, required every school (grades 1–12) to establish a school library as a reading and learning center, and to employ a teacher-librarian (*shisho-kyoyu*), with a supplementary provision that stated that “the placement of a teacher-

librarian is optional for the time being.” Many schools did not have teacher-librarians for nearly 50 years until 1997 when the supplementary provision was revised to require all schools with 12 or more classes to employ a teacher-librarian by March 31, 2003. According to Article 5 of the School Library Law, a 10-credit training program for teacher-librarians can be administered by colleges, universities, or boards of education in compliance with the Minister of Education, Culture, Sports, Science and Technology (MEXT). Since 1997, many schools have started to employ teacher-librarians, however, in most cases schools have asked existing teachers to obtain the teacher-librarian certificate through intensive summer courses rather than appoint new teacher-librarians. In many cases, the teacher-librarian remains a full-time teacher and his or her teaching responsibilities are not reduced despite being appointed as a teacher-librarian.^[6] However, an increasing number of schools employ clerical staff in school libraries (collectively called *gakko-shisho*) who generally manage collection development, circulation, and many other business practices. Computers were introduced into school libraries in the 1980s. According to a MEXT survey, nearly 40% of primary and

Table 2 Statistics of public libraries.

	Number of libraries	Number of full time staff	Number of books borrowed	Number of holding
2002	2,711	15,284	546,287,000	310,165,000
2003	2,759	14,928	571,064,000	321,811,000
2004	2,825	14,664	609,687,000	333,962,000
2005	2,953	14,302	616,957,000	344,856,000
2006	3,082	14,070	618,264,000	356,710,000

Source: Statistics by JLA, 2006.

lower secondary schools, and 70% of upper secondary school libraries have automated catalogs. Table 3 shows some statistics on school libraries in Japan.

Special Libraries

In 2007 the membership institutions of the Special Library Association consisted of 560 libraries belonging to local and central governments, private companies, and research institutes. Despite the fact that about a quarter of these libraries are small, one-person libraries, special libraries provide diverse and unique collections and services. Many of their services are accessed primarily online.

The followings are major special libraries in various fields.

Science and technology

The Japan Science and Technology Agency (JST, <http://www.jst.go.jp/EN/index.html>) was reorganized in 2003, absorbing a former organization known as JICST (1957–1996); it is now providing various services such as J-STAGE, an electronic journal support system, photocopying service, and translation services. JST services are used broadly by research libraries and natural science researchers both domestically and abroad.

Medical sciences

The IMIC (International Medical Information Center, http://www.imic.or.jp/about/outline_e.html) is located in Tokyo, and is the national document supply center of medical information. It succeeded the Kitasato Memorial Medical Library of Keio University in 1972, collecting and disseminating highly sophisticated medical information.

Table 3 Average holdings of public school libraries as of December 2005.

Primary school	7,312 volumes
Lower secondary school	9,040 volumes
Upper secondary school	21,771 volumes

Source: Statistics by MEXT.

Business

JETRO (Japan External Trade Organization) Business Library (<http://www.jetro.go.jp/library/>) used to be a government agency before it was reorganized as an independent administrative agency (IAA) in 2004. It has offices in Tokyo and Osaka, and provides business information on a country-by-country basis for the advancement of Japanese trade.

Another JETRO library is at the IDE (Institute of Developing Economics) Library (<http://www.ide.go.jp/English/Library/>), located near Tokyo, with collections on economics, politics, and social issues of regions in Asia, Middle East, Africa, Latin America, Oceania, and Eastern Europe.

Braille library

The Japan Braille Library (Nihon Tenji Toshokan, <http://www.nittento.or.jp/>) is a social welfare corporation, founded in 1940 by Kazuo Homma (1915–2003). It produces 3000 volumes of Braille and recorded books yearly, and provides a free recorded books service. In 2004, it started Internet service of DAISY contents. There are also more than 200 Braille libraries and public libraries that make Braille books available to the public in Japan.

Art and museum library

Following the 1986 IFLA conference in Tokyo, the Japan Art Documentation Society (<http://www.soc.nii.ac.jp/jads/eng/index.html>) was established by curators and librarians in 1989 to meet the needs of museum libraries. In 2004 the ALC (Art Libraries' Consortium) was founded by eight museums in Tokyo. They have a cross-searchable online-public access catalog.

Japanese studies

The Japan Foundation is a renowned foundation among Japanese studies scholars, offering various cultural exchange programs, Japanese language teaching, and library service. The JFIC (Japan Foundation Information Center, <http://www.jpf.go.jp/e/jfic/lib/index.html>) is in Tokyo and there are two other libraries in other parts of Japan. It also operates 18 JF libraries outside Japan, which function as gateways to Japanese language and culture.

Digital Library Collections and Services

The digital library dates back to the 1980s with the advent of CD-ROM. During the 1990s, the focus of discussion moved from electronic publishing to “digital library” or “electronic library” on the Internet. In the 2000s, some larger public, university, special libraries began offering rare book images, institutional academic documents, and books with expired copyright protection. In addition to the digital library created by the National Diet Library as mentioned above, the following libraries also offer digital library collections to public.

The University of Kyoto Library started its digital library (<http://edb.kulib.kyoto-u.ac.jp/minds-eu.html>) in 1998, and contains images of rare books registered as national property, some texts of the university’s publisher, theses, and a repository of articles and reports published within the campus. EDMC (Great Hanshin-Awaji Earthquake Disaster Materials Collection, <http://www.lib.kobe-u.ac.jp/eqb/e-gallery.html>), created by Kobe University Library in 1995, is a one-of-a-kind digital gallery on its Web site, containing invaluable records and images with a risk management perspective.

IPDL (Industrial Property Digital Library, http://www.ipdl.inpit.go.jp/homepg_e.ipdl) was created in 2000 by The Japan Patent Office. Patents, utility models, trademarks, and design can be searched on the Internet, and the patent gazettes and other industrial property information can be accessed at the reference library of the National Center for Industrial Property Information and Training.

Aozora Bunko (Blue Sky Library, <http://www.aozora.gr.jp/#main>) is the digital library that is the best-known among the general public; it was created by Eiji Noguchi in 1997 and now contains thousands of copyright-expired Japanese books (mainly in literature).

Education for Library and Information Science

Currently, there are five types of library and information science (LIS) education offered at colleges and universities in Japan.

- Librarian (*shisho*) training provided by more than 250 colleges and universities, during the regular academic year and as an intensive summer program.
- Teacher-librarian (*shisho-kyoyu*) training provided by more than 100 colleges and universities, during the regular academic year or as intensive summer programs.
- Undergraduate LIS majors offered by fewer than 10 colleges and universities.
- Master-level LIS programs offered by eight colleges and universities.
- Doctoral level LIS programs offered by six colleges and universities.

These courses or programs produce approximately 12,000 qualified *shisho* and 12,500 qualified *shisho-kyoyu* every year. The majority are trained at an undergraduate level. The knowledge and skills held by graduates of these programs are quite diverse while, employment opportunities for full-time librarians in 2007 were quite limited.

The legal basis of Japanese LIS education was established by The Library Law (enacted in 1950) and The School Library Law (enacted in 1953). Formal LIS education programs are given mainly by colleges or universities in compliance with the MEXT, as training programs for librarians of public libraries and teacher-librarians of school libraries. Courses, credit units and other guidelines are specified by Ministry rules. There is no formal education system in place for information professionals in academic and special libraries. The certificate for *shisho*, which was intended for public library professionals, is considered the basic requirement for other types of library professionals in Japan.

The first comprehensive program for library education at the university level was established in 1951 at Japan Library School of Keio University, under the auspices of the American Library Association. According to MEXT, 13 colleges and universities offer Intensive Summer Courses of formal librarian training, while seven offer correspondence training courses.

In the area of continuing education in LIS, The Graduate School of Library and Information Science at Keio University established a new course for library workers in 2004, in order to give them opportunities for continuing education. Some other colleges and universities, such as Tsukuba University or the University of Tokyo are also establishing new tracks for continuing education at the graduate level, while the vast majority of librarians in Japan have a bachelor’s degree, there will be more librarians with master’s degrees in LIS in the future, especially in academic libraries. MEXT, National Diet Library, Tokyo Metropolitan Library, and some other major libraries also offer various staff training programs throughout the year.

One of the biggest issues in education and training for librarianship in Japan is how to strengthen the profession and to improve the status of librarians in society. Based on the shared understanding of current problems in LIS, the Library and Information Professionals and Education Renewal, a 3-year research project to study LIS education systems and curricula in Japan, proposed two areas for reform. They include: 1) The introduction of an independent LIS examination as a formal quality-assuring mechanism for overall education of information professionals; and 2) provision of an integrated curriculum for information professionals overall.^[6–8]

Professional Associations

According to *Library Year Book* 2007, there are about 90 national associations, councils, or societies related to

libraries. Among them, the JLA is the largest and most comprehensive association in the field of libraries in Japan, representing all types of libraries and related organizations in Japan.

JLA (*Nihon Toshokan Kyokai*, JLA, <http://www.jla.or.jp>) was founded in 1892, and promotes the development of libraries and librarianship in Japan. Its activities have been supported by member librarians throughout Japan for over a century. JLA consisted of 5100 individual members and 2600 institutional members as of 2006. JLA has been a member of IFLA since 1929. The mission of JLA consists of four basic policies: 1) to be the national information center for all libraries and librarians in Japan; 2) to be an education, training, and career development center for librarians; 3) to cooperate with, and coordinate all kinds of libraries and library organizations; and 4) to promote and support international relations activities with libraries and librarians around the world.

The all-Japan Library Conference is held annually in different cities around the nation, and is hosted by a prefectural library and regional communities. There are six divisions (Public Libraries, University Libraries, Junior College Libraries, School Libraries, Special Libraries, and Education), and about 25 committees and working groups (Library Policies, Library Management, Copyright, Intellectual Freedom, Preservation and Conservation, International Relations, Services for the Handicapped, Library Services for Children, etc.). JLA started publishing its monthly organ, *Library Journal* (*Toshokan Zasshi*) in 1907. It also publishes an average of 20 new monographs each year, as well as *Libraries Today* (*Gendai no Toshokan*, a quarterly), *Basic Subject Headings*, *Guide to Japanese Reference Books*, *JLA Librarian's Glossary*, *JLA Librarians Handbook*, *Library Year Book*, and *Statistics on Libraries in Japan*.

The following is a list of some leading associations related to libraries in Japan:

1. Japan Medical Library Association: JMLA (*Nihon Igaku Toshokan Kyokai*). Founded in 1927, it became a nonprofit organization in 2003 (<http://wwwsoc.nii.ac.jp/jmla/index.html>).
2. Japan Association of Private Universities Libraries: JAPUL (*Shiritsu Daigaku Toshokan Kyokai*): Founded in 1938. Membership in 2006 was 496 private university libraries, covering approximately 91% of total number of private universities in Japan (<http://www.jaspul.org/>).
3. Japan School Library Association: JSLA (*Zenkoku Gakko Toshokan Kyogikai*). Founded in 1950, it is the most comprehensive institute in the field of school libraries (<http://www.j-sla.org.jp>).
4. Japan Special Libraries Association: JSLA (*Senmon Toshokan Kyougikai: Sentokyo*). Founded in 1952, it publishes the Directory of Special Libraries, Japan (<http://www.jsla.or.jp/eng/index.html>).
5. Japan Association of National University Libraries: JANUL (*Kokuritsu Daigaku Toshokan Kyokai*). Founded in 1954, it is a membership organization comprising mainly libraries of national universities in Japan, totaling 92 libraries and library facilities (<http://wwwsoc.nii.ac.jp/anul/index-e.html>).

ARCHIVES

Overview of Japan's Archives Today

In Japan today, a large number of archives exist as physical entities, irrespective of whether they are independent organizations or not. Not only do these contribute to affairs in a variety of sectors, including academia, culture, government administration, and business, but they also preserve precious historical materials. In Japan, however, there is no system of central management for working documents in record centers, archives, or the like, either in the public or the private sector. Instead, a system of decentralized management by each department creating documents is preferred. As a result, archives on an organized level have not developed on a scale commensurate with Japan's national strengths in culture or economy, and many remain quite small. A system of public archives for documents not in current use has been created in order to guarantee public access to information (a founding principle of democracy in Japan). This comes along with the Act on Access to Information Held by Administrative Organs (1999), which guarantees access to documents in current use. An overview of present situation in Japan will be introduced below with a focus on public archives that have been established and are broadly perceived by the public as centers for access to documents not in current use.

The National Archives of Japan

The National Archives of Japan were established in July 1971 as a body affiliated with the Prime Minister's Office. Later renamed the National Archives of Japan in April 2001, it functions as an Independent Administrative Institution with the mandate to ensure the appropriate preservation and use of public documents, which are regarded as important historical materials designated for deposit by government institutions.

The holdings of the National Archives of Japan are broadly divided into: 1) public documents of state institutions, starting with the *Dajokan* after the Meiji Restoration; and 2) the Cabinet Library, mainly consisting of ancient Japanese and Chinese classical books passed down since the archives of the Shogun during the Edo era. As of March 31, 2007, its holdings consisted of 625,996 public document files and 479,500 ancient and classical books. Of these, 99.7% have been cataloged in a database, which

can be accessed via the Internet (<http://www.archives.go.jp/>). In fiscal 2006, the Archives received 29,420 visitors. The institution employs a staff of 42 regular employees and about twice that number of nonregular employees. The main office is inside Kitanomaru Park (next to the Imperial Palace in Tokyo), while there is also a Tsukuba Annex in Ibaraki Prefecture and the Japan Center for Asian Historical Records in Chiyoda Ward, Tokyo. The total floor area of the three buildings is about 6900 m² (Figs. 5 and 6).

One of the branch facilities of the National Archives of Japan is the Japan Center for Asian Historical Records. This is Japan's first full-scale digital archive specializing in public documents on the relationship between Japan and surrounding countries in the modern and contemporary eras (<http://www.jacar.go.jp/>). It houses some 12.5 million images of public documents and documents archived by the Imperial Army and Navy, the Ministry of Foreign Affairs and the National Archives of Japan up to 1945. These are provided in digital form, in both English and Japanese. Over the past 5 years or so, the Center has received more than 3 million access requests from both Japan and abroad.

The main activities undertaken by the National Archives of Japan, including this Japan Center for Asian Historical Records, can be summarized under the following six headings:

- Promoting digital archiving.
- Strengthening training systems for national and local government personnel.
- Participating in and contributing to international public archive activities.
- Locating and providing information on the location of historical public documents, etc.
- Conducting surveys and research activities aimed at raising the level of public archive activities.

- Creating a database and providing data on Asian historical materials.

Meanwhile, in cooperation with the Cabinet Office (the body with jurisdiction over the National Archives), research aimed at introducing an intermediate repository system is being vigorously pursued, as well as research on the transfer of public documents created using electronic recording media. The aim in doing so is to promote smoother transfers of public documents from the various government ministries and agencies.

Public Archives of Local Authorities

As of April 2007, there were approximately 1800 local authorities in Japan, but of these, only 50 authorities maintain public archives. Specifically, public archives are maintained by just 30 out of 47 prefectures, 7 of the 15 cities designated by government ordinance and, of the other authorities, 13 municipalities. As for the others, in many cases, a division in charge of public documents manages public documents based on a predetermined number of storage years, as stipulated in file management ledgers, etc.

The first local authority to create public archives was Yamaguchi Prefecture in 1959. Public archives generally come under the jurisdiction of the General Affairs Department or the Board of Education, and the scale is invariably small, with a staff of fewer than 20 (including both regular and nonregular employees). Each local authority undertakes its own personnel management of archivists. Despite a somewhat difficult administrative and funding environment, local public archives are gradually increasing in number, at the rate of one or two a year.

Fig. 5 Photo of National Archives of Japan, Main office.

Fig. 6 Photo of Stacks of National Archives of Japan.

College and University Archives

At the start of the twenty-first century there were about 700 colleges and universities in Japan. Of these, mainly large colleges and universities with long histories vigorously moved to create college and university archives starting in the 1980s in connection with the publication of university histories. A survey of college and university archives conducted by the Japan Association of College and University Archives of Japan in 2003 attracted responses from 84 colleges and universities. From this, we may assume that at least 84 colleges and universities maintain college and university archives.

University archives in some cases have focused on the collection and classification of historical and other materials related to the personal archives of the founders—particularly in the case of private universities. Recently there has been a growing interest in the management and preservation of university management documents that are no longer current.

Corporate and Other Archives

In many cases, archives kept by private companies have been established in connection with the compilation of company histories and they have sometimes been part of special libraries. Since the 1970s, there has been a progressive trend in Japanese industry to compile and publish company histories. As a byproduct, business archives have been accumulated and archive organizations created. However, this creation of corporate and other private-sector archives is highly sensitive to the economic

environment. After peaking about 1990 at about 140, business archives started to decline along with a decline in the compilation of company histories. Today the number has fallen to about 100. Moreover, there are hardly any private-sector organizations that hire business archivists as specialist professionals. The majority of these private-sector archives belong to the Business Archives Association (BAA), which was established in 1981.

Laws Governing Archives

Two laws directly related to archives have been enacted in Japan. The Public Archives Law was enacted in 1987 and came into force a year later, while the National Archives Law was enacted in 1999 and took effect in 2000. A brief overview of these two laws will be given below.

On the problem of information disclosure, which is closely related to archive activities, the Information Disclosure Law (or, to use its formal title, the “Act on Access to Information Held by Administrative Bodies”) was enacted in 1999 and came into force in 2001. Some commentators have pointed out that this law is incomplete, in that it only deals with aspects of the disclosure of public documents. They are calling for the enactment of a Public Documents Management Law (tentative name) to address these problems.

The Public Archives Law

The purpose of the law is to stipulate necessary matters related to public archives, in awareness of the importance of archiving public documents and records as historical

materials and making them available for use. The law consists of seven articles, and is said to have a strong tone of moral guidance. Among these seven articles, there are rules to the effect that the government should strive to furnish or facilitate the funds needed by local authorities to set up public archives, and that, in addition to a president, special research officers, and other necessary officers should be appointed. As for the necessity of special research officers, however, Article 2 of the Supplementary Provisions states, as "Exceptions to the Provision regarding Special Research Officers" that special research officers do not need to be appointed to public archives for the time being.

The National Archives of Japan Law

This is an organizational law for the National Archives of Japan (established as a department of the Prime Minister's Office in 1971), enacted upon its conversion to an independent administrative institution. It consists of 16 articles, which provide for the title, purpose, and scope of operations of the National Archives of Japan as an independent administrative institution undertaking activities based on the regulations in the Public Archives Law. They also provide for the appropriate preservation and use, of public documents. In this law, the term "government documents and records" is used to mean government documents and other records excluding those in current use by organs of the state. As the scope of its operations, meanwhile, the law provides that the National Archives of Japan shall preserve and make available for public use governmental documents and records that are of importance as historical materials. To that end, the National Archives is mandated to gather, classify, and provide information, provide professional and technical advice, conduct research and give training.

Archive-Related Societies and Associations

Academic societies

There are two academic societies related to archive studies, namely the Records Management Society of Japan (established in 1989) and the Japan Society for Archival Science (JSAS) (established in 2004). The Records Management Society of Japan was established with the intention of diffusing and disseminating the concept of record management in Japan, mainly among librarians, archivists, filing consultants, and other people with interest in the management of documents in current use. Its present membership is around 300. It holds a Research Convention combined with its Annual Conference, and publishes the semi-annual *Record Management (Journal of the Records Management Society of Japan)* as a peer-reviewed journal. Besides this, it is currently lobbying hard for the enactment of a Public Documents

Management Law. Internationally, it enjoys a close relationship with the Tokyo branch of the American Records Management Association (ARMA).

The JSAS was formed by researchers in the archives field and in the field of historical studies. Some of its leading members have studied overseas and have expert knowledge of innovative trends in archival science around the world. As such, there are now increasing cases of research activities conducted jointly by JSAS, many of whose members are interested in documents not in current use (based on the theory of lifecycle of records) and the Records Management Society of Japan, which is principally concerned with documents in current use. The outcome of such research has occasionally been published. Besides holding research presentations twice a year, the JSAS also publishes the annual *Journal of the Japan Society for Archival Science* as a peer-reviewed journal. It, too, has about 300 members, the majority of whom are archive-related researchers and postgraduate students. The principal focus of its activities is on establishing and diffusing archival science in Japan. For the time being, this involves an effort by its core members to consolidate and develop the foundation for a course majoring in archival science at the Graduate School of Gakushuin University in Tokyo.

Associations and organizations

Japan Society of Archives Institutions (JSAI): This is a national organization of institutions for the preservation and use of archives, etc., established in 1976. It consists of institutional members and individual members who work for them. Initially, it had about 160 institutional members and 270 individual members, and was the only organization in Japan that promoted the archive movement. As a result, it has undertaken a broad range of survey and research activities, communication and coordination activities, and others fundamental to this movement. Now that archives have achieved a degree of diffusion and establishment in Japanese society, however, related academic associations have been formed while institutions and organizations for communication and coordination have also been established. Furthermore, the public archives of local authorities, which used to serve in promoting activities, have become somewhat passive owing to the constraints on local government finances. JSAI holds an annual convention, at which features research presentations and training programs, in addition to the general meeting for its operational management. It publishes the journal *Records and Archives* (annual), of which 17 had been issued by March 2007.

Business Archives Association (BAA): This is a national organization concerned with business archives, which was established in 1981. In recognition of the social and historical value of business archives, the association's purpose is to conduct surveys and research on the gathering,

preservation, and management of business archives, and to improve practice in these areas. According to BAA's regulations, its operations include publishing journals, holding research meetings, touring-related institutions, and nurturing business archivists (business archive managers). It also promotes international exchange between Japan and China. Its publications include the occasional research bulletin *Kigyo to Shiryō (Business and Archives)*. Its membership initially consisted of 55 institutional members and 20 individual members, but today these have increased to about 100 institutional and 60 individual members.

Japan Association of College and University Archives: This association was formed in 2005, when existing liaison groups responsible for college and university history in East and West Japan merged. At the time, its membership consisted of 83 universities and 40 individual members. The purpose of its activities is to provide a forum for information exchange, to promote research on college and university history, and to work for improvement in practice among its members. Its day-to-day activities are still conducted separately by its predecessor organizations, i.e., the East Japan Branch and the West Japan Branch, and the association's only collective activity is its yearly national convention.

Systems of Education and Training

Systems of education and research in universities

It would be fair to say that the training of archivists in Japan is still in the process of being established. Many people who have worked as archivists are involved in managing archive materials in addition to their historical research, and the amount of this archival work has increased. Consequently, as of 2007, there were no faculties or departments of archival science in Japanese universities. The only course that exists on archival science is offered by the Faculty of Cultural Information Resources at Surugadai University. Starting in April 2008, Master's and Ph.D. courses majoring in archival science were to be set up in the Graduate School of Gakushuin University. However, there is no undergraduate course that allows students to major in archival science. In Japan, therefore, archival science is not taught as part of library information studies in the departments of undergraduate faculties or graduate schools, as is the case in other countries.

Systems of on-the-job training

To compensate for the lukewarm attitude of Japanese universities toward archival science, on-the-job training programs are essential. Training programs that are held on a regular basis every year and the programs that are considered authoritative are those of the National Archives of Japan and the National Institute of Japanese Literature. Besides these, there are isolated training programs offered

by public archives and others in various parts of the country.

Training programs of the National Archives of Japan: The National Archives of Japan is planning to offer five different training programs for employees and related personnel already working in archives. These training programs may be broadly divided into two types:

1. Training aimed at developing archive literacy, with 1 day of on-the-job observation and 3 days of training aimed at ordinary non-specialist personnel involved in records management work in public institutions; and
2. Programs designed to train as archivists selected staff who need greater expertise because they are working as specialists in records management in public institutions. The latter will be divided into elementary grade (1 week), intermediate grade (4 weeks), and advanced grade (3 days). The non-specialist training is to be given to about 60 trainees every year and the specialist training to about 70. Training will be delivered by lecturers selected from universities, administrative bodies and others, in addition to the archivists of the National Archives of Japan. The style of training basically is done through classroom sessions in the main office of the National Archives of Japan. The trainees of intermediate grade are required to complete a final paper equivalent to graduate or master thesis in universities.

Archives College programs: Workers in the field are familiar with the name of the "Archives College," a term applied to archives management seminars offered by the National Institute of Japanese Literature. This Institute is a part of the National Institute for the Humanities in the Inter-University Research Institute Corporation. This training consists of a long-term course and a short-term course, the former lasting for 6 weeks divided into two phases and held at the National Institute of Japanese Literature in Tokyo. The short-term course lasts for 2 weeks and is held in regional locations. The fixed capacity of trainees is 35 for both long-term and short-term courses, and lecturers are invited from other universities, etc., besides the full-time instructors of the National Institute of Japanese Literature. Graduate students majoring in archival science are permitted to take part in the long-term course.

MUSEUMS

Modern Museums in Japan

National museums *hakubutsukan* and *bijutsukan*

The history of modern museums in Japan dates back to the Meiji era. In 1872, an exhibition was organized under the name of the Museum of the Ministry of Education of the Meiji government. The exhibition was opened at the

Taiseiden Hall in *Yushima Seido* with a view to making preparations for the Vienna World Exposition to be held the following year. As a result, an identity was given to the museums as exhibition-oriented facilities housing and exhibiting *hakubutsu*, meaning in Japanese, a variety of domestic articles to encourage new industries. The Japanese word for museum, *hakubutsukan*, literally means a house collecting various objects. *Hakubutsukan* has come to have a meaning different from the original word in the European languages.

When the first National Industrial Exhibition was held in 1877, the arts and crafts products were displayed in what was called *bijutsukan*. Since then, the Japanese *hakubutsukan* together with *bijutsukan* has been used to refer to art museums. During the late nineteenth century the *hakubutsukan* museums began to collect and show traditional cultural artifacts, although initially other kinds of products were also displayed. The Tokyo National Museum has kept the name *hakubutsukan* in Japanese even though it is a museum of fine art. It is currently under the Agency for Cultural Affairs which reports to the ministries in charge of internal affairs (Fig. 7).

Another type of institution which was called the “educational *hakubutsukan*” museum was set up under the control of the Ministry of Education with the goal of presenting learning materials related to natural science, such as samples of plants, stones, or rocks. This museum has grown into the current National Museum of Nature and Science, Tokyo. In the meantime, museums with increased emphasis on research activities were established under the control of the Academic and International Affairs Bureau of the Ministry of Education. These museums are the National Museum of Ethnology, Osaka, and the National Museum of Japanese History. These state-run museums have been reorganized as independent

corporations since 2001. As of 2007, the reorganization and consolidation of the museums were as follows:

The National Institutes for Cultural Heritage (Independent National Agencies) consist of the

- Tokyo National Museum,
- Nara National Museum,
- Kyoto National Museum,
- Kyushu National Museum,
- National Research Institutes for Cultural Properties, Tokyo and
- National Research Institutes for Cultural Properties, Nara.

The National Museums of Art (Independent National Agencies) include

- the National Museums of Modern Art, Tokyo, and Kyoto,
- the National Museum of Western Art,
- the National Museum of Art, Osaka, and
- the National Art Center, Tokyo.

National Institutes for the Humanities (Inter-University Research Institute Corporations) include

- the National Museum of Ethnology,
- the National Museum of Japanese History, and
- the National Institute of Japanese Literature.

Hakubutsukan and *Bijutsukan* Museums run by local governments, foundations, and private companies

After the first museums were founded by the Ministry of Internal Affairs, local governments founded various types

Fig. 7 Main Gallery of Tokyo National Museum, copyright, TNM Image Archives.

of museums and organized exhibitions and fairs showing both contemporary products and antiquities. Most of them, however, were exhibitions of articles or products with only a few that developed into full-scale museums. The Ministry of Education set up museums for educational purposes. This encouraged the foundation of such museums in regional cities, but this initiative was short lived. In the 1910s, “popular” museums were opened and in the latter half of the 1920s, many provincial museums were founded for the promotion of local education. Both types of museums were strongly supported by nationalist movements. Apart from these, it should be noted that there were also private initiatives to create museums, such as the Attic Museum founded in 1921 by Keizo Shibusawa (now the Institute of the Study of Japanese Folk Culture, Kanagawa University) and the Japan Folk Crafts Museum founded in 1936 by Muneyoshi Yanagi. In 1897, the Old Temples and Shrines Conservation Law was promulgated. Prompted by this law, temples and shrines preserved collections of ancient artifacts to show to the public.

In the field of fine art, the Tokyo Metropolitan Museum was founded in 1926 as the first local government-run *bijutsukan* museum. This museum is the predecessor of both the Tokyo Metropolitan Museum and the Museum of Contemporary Art, Tokyo. In 1917, a foundation-run museum was founded: Okura Shukokan Museum of Fine Arts, an institution that collected Asian fine artworks.

As for private museums, in 1930 the Ohara Museum of Art was opened as the first Japanese museum featuring Western art. In 1952, Bridgestone Museum of Art was opened to the public. These museums are now managed by foundations. Some private enterprises also run their own museums, an example being the Printing Museum in Tokyo (2000) established by Toppan Printing Co. A survey shows that there are a total of about 900 corporate museums in Japan.

Following the examples of the Library Decree (1899) and Revised Library Decree (1933), efforts arose to establish a museum decree. Such efforts were given added impetus when the Museum Promotion Society (renamed Japanese Association of Museums in 1931) was set up. However, it was not until 1951 that a museum law was promulgated. It came into force the next year, and was based the principle of the Fundamental Law of Education under the new constitution. Museums are now under the control of the Lifelong Learning Bureau of the MEXT.

The museums under the law are classified as below:

1. Registered museums meet specified requirements such as the employment of curators and storage of reference materials. The public museums of local governments are under the control of local education boards and are outside the control of MEXT. As for museums set up by corporations, the law covers only those established by special corporations such as the Japanese Red Cross Society and religious corporations.

2. The museum-equivalent institutions operate similar to museums. In the museums established by local governments, those authorized by heads of the local governments are included.

Museums not covered by the law are:

3. Museum-like institutions. A 2005 survey showed that the total number of museums was 5614.
 - Category (1): 865 museums (126 run by prefectures, 344 by wards and cities, and 263 by towns and villages).
 - Category (2): 331 institutions (national two, prefectural 26, ward- and city-run 94, town- and village-run 12).
 - Category (3): 4418 institutions (national 127, prefectural 266, ward- and city-run 1919, town- and village-run 1166).

Statistics show that the overwhelming majority of institutions are in Category (3) and the ones covered by the museum law, Categories (1) and (2), are about one-fifth of the total (source: Social Education Survey Report 2005 published by the MEXT).

University museums

As of 1999 there were 145 university-run museums around Japan, including facilities called reference rooms or historical materials rooms, and botanical gardens. The time-honored examples to note in this regard are the Agricultural Department Museum of Hokkaido University (founded in 1882), Tsubouchi-Memorial Theater Museum of Waseda University (1928), and Meiji University Museums including the Criminal Museum (1929). Various departments of the state-run universities including the imperial universities have been collecting samples and reference materials in many fields. In 1995, the Science Council, an advisory board to the Minister of Education, submitted a report encouraging the establishment of museums in the universities. Tokyo University, the first among the national universities, established a multidisciplinary museum in 1997, as the successor to a university museum opened in 1961 with 6.5 million items and reference materials). This was followed by Kyoto University (multidisciplinary museum in 1997, 2.5 million pieces) and Kyushu University (multidisciplinary museum in 2000, 6.5 million items).

Many arts universities also include museums. For example, Musashino Art University founded in 1966 an art reference materials library, which includes a museum. In 1999, Tokyo University of Fine Arts and Music opened a museum, which keeps art objects collected over a long period extending to before the foundation of Tokyo Art School, the predecessor of the university (founded in 1887). The art objects were once stored in a university

library and then in the art reference materials facility along with music-related reference materials.

Professional Staff and Museum Libraries

Professional staff

The Museum Law provides that registered museums must employ professional staff, *gakugei-in*. The Japanese term used for curator, *gakugei-in* literally means a person in charge of *gaku* or learning and *gei* or art. “*Gakugei-in*” do not have exactly the same significance of curators, keepers, or conservators in the European languages. The number of the curators totaled 2898 in 865 museums as of 2003, which is 3.4 curators per museum on average. Combined with the staff of the museum-equivalent institutions, the total number of them amounts to 3827 in 1196 museums (3.2 curators per museum on the average). The museum-like institutions are far more poorly staffed with 2397 curators in 4418 museums (0.5 curators per museum on the average).

The museums, in principle, must be provided with the professional staff other than the curators. However, the Japanese curators in the museums are commonly forced to perform various other functions as well. Most museums tend to employ librarians, educators, conservators, registrars, and other professional workers. At present, staff strength is slowly increasing, but remains far below the required level. A few of the museums, mostly national museums, are staffed with full-time workers specialized in library management and information system construction. In most cases, the library of the museums is managed by a part-time librarian.

Museum libraries or art libraries

In the area of museum libraries, development of those in fine art museums has been most remarkable.

The first full-fledged art library in Japan was founded in 1930 by the Imperial Fine Arts Academy (now National Research Institute for Cultural Properties, Tokyo). Then, the Library and Museum of Musashino Art University (1966) and the art library of Tokyo Metropolitan Art Museum (1976) followed suit. Tokyo National Museum built the independent Research and Information Center* in 1984. The establishment of these museum libraries was followed by

- Yokohama Museum of Art* (1989),
- Aichi Arts Center (1992),
- Tokyo Metropolitan Museum of Photography* (1995),
- Museum of Contemporary Art, Tokyo* (1995, which inheriting the reference materials collected by Tokyo Metropolitan Art Museum),
- Hyogo Prefectural Museum of Art (2002),
- National Museum of Modern Art, Tokyo* (2002),

- National Museum of Western Art* (2002),
- Museum of Modern Art, Hayama (2003) and
- National Art Center, Tokyo* (2007).

In spite of the different characters of these museums, the seven museum libraries* above have organized an art library consortium, presenting, via Internet, a cross-search service of their own books, magazines, etc. (<http://lalc.opac.jp>)

Museum-Related Societies and Associations, and Education and Training Systems

Societies and associations

The Japanese Association of Museums, a nationwide professional body (about 1900 institutions and individuals) was organized in 1928 initially as the Museum Service Promotion Society. This association aims at promoting lifelong learning activities, and at conducting investigation and research for the development of museums. It publishes a monthly journal *Museum Studies*. There is another association called the Japanese Association of Zoos and Aquariums (membership of 160 organizations). In the art-related field, the Japanese Council of Art Museums (membership: 350 museums) was founded in 1951, and the Japan Association of Art Museums started its activity in 1982 with membership of 120 museums. The former association has as its purpose the exchange of information and professional training; it is composed of the national, public, and private art museums. The latter has membership of the public art museums with the main purposes of coordinating traveling exhibitions and encouraging art-related activities.

As for societies, the Museological Society of Japan has about 360 members, and publishes the *Journal of the Museological Society of Japan* twice a year. In 1995, the Japan Museum Management Academy was set up, and had a membership of 400 individuals and 40 organizations. The academy publishes the *Annual Bulletin of Japan Museum Management Academy*. In this connection, the Japan Society for Exhibition Studies (about 500 members) was established in 1982. The society publishes a semi-annual journal *Tenjigaku*. Founded in 1989, the Japan Art Documentation Society (about 300 individual members) is engaged in library- and archive-related activities, with emphasis placed on promotion of museum documentation services. The society has an official annual journal, *The Bulletin of the Japan Art Documentation Society*.

Education and training systems

To become a curator requires completion of a number of credit units in university curatorship courses or

successfully passing a national examination. In fact, 99% of the qualification is dependent on the credits obtained by university courses: 12 units from 8 subjects. The number of the units needed to become a curator is less than that for a librarian. The need for improvement of curator education has been pointed out repeatedly.

At present, more than 200 universities in Japan have curatorship courses. About 10,000 students receive the qualification annually. However, only about 400 have been employed per year in recent years. As mentioned above, museums, and museum-similar institutions in particular, are not staffed with the required number of curators. To solve this problem, it will be necessary to improve the basic abilities of curators. In this connection, there have not been university faculties or departments specializing in curatorship, as is the case with librarians. Improvement in the quality of curators is a serious problem, which should include programs at the graduate level.

With regard to training of museum workers, professional courses include a nationwide 3-week course for museum workers by the National Institute for Educational Policy Research; a 1- to 4- week (period variable with the fields) course for the archeologists offered by the National Research Institute for Cultural Properties, Nara; a training course (2-year course of 1 week a year) for historical and ethnological staff by the National Museum of Japanese History; and a 2-week training course for curators of the museums in charge of conservation by the National Research Institute for Cultural Properties, Tokyo.

Problems Concerning Museums

Computerization and evaluation of management

Since opening to the public in 1977, the National Museum of Ethnology, Osaka, has had an artifact catalog database system and video system "videothèque," which are well known around the world. From the mid-1990s, many museums built up in-house computer systems. Today, the museums provide data on their collections via Internet. However, a nationwide collection search system has not yet been realized. This may be because most of the museums tend to stress exhibitions and to think little of collection building and cataloging. According to a survey conducted by the Japanese Association of Museums, 53% of museums record nearly all the data in an accession register, and 22% of them keep a so-called "collection catalog," which covers all the data (source: "Comprehensive Survey Report of the Museums of 2004).

The administrative reform starting in the 1990s influenced and attracted considerable interest from museums. In response to this reform movement, the Japan Museum Management Academy was founded. Since 2001, the national *hakubutsukan* and *bijutsukan* museums have been reorganized as an independent national agency.

The revision of the Local Autonomy Law in 2003 provides for the use of a designated administrator in the services of local governments. According to this law, 93 museums (as of 2005) decided to consign part of their work to a private company or nonprofit organization. Some people say such changes may damage the regular service level that the museums have so far maintained. More museums are going to introduce evaluation systems by themselves or by third party to enhance the restructuring. For example, Asahiyama Zoo of Asahikawa City has for 10 years monitored the remarkable renovation of its unique animal viewing system. Opened in 2004, the Twenty-first Century Museum of Contemporary Art, Kanazawa, features contemporary art, which is considered hard to appreciate by many people. Both zoo and museum together these two have succeeded in attracting more than 1.5 million guests per year although they are in the less populated local cities. Paying close attention to users, the two institutions are highly evaluated for their management abilities.

Movements toward revision of the Museum Law

In 2007, MEXT published a report for the revision of the Museum Law, in which the Ministry points out advances in registered museums and enhancement of education for curators. As mentioned above, the registered museums and museum-equivalent institutions are now only about one-fifth of the total institutions. The Ministry seeks to create a legal framework to improve as many institutions as possible, raising their status to the registered-museum level. In the area of curatorship, MEXT will try to enhance the ability of curators. In this context, curators will be qualified in fundamental curatorship when finishing the essential courses in university, regular curatorship when achieving the training course in a graduate program, and superior curatorship after a period of work in museum.

When the museum law was enacted more than 50 years ago, there were about 200 museums. Now, the number of museums has reached more than 5600. Furthermore, the Fundamental Law of Education, revised in 2006, puts great value on the lifelong learning principle. The important role of museums is once again being discussed. The registration standard of museums will be based mainly on abilities required for "management," "collection," and "communication," with reduced emphasis on the period of open days per year, one of the former registration standards. With respect to the requirements for curators, more emphasis will be placed on communication-related ability than the conventional abilities of research and exhibition. In addition, the national museums (Independent National Agencies), university museums, and non-profit private museums, which are not covered by the Museum Law, will be taken into consideration to be treated like

registered museums. The cooperative network of museums in Japan is being realized.

CONCLUSION

Libraries and document collection have a long history in Japan, based on a fundamental respect for written information and knowledge. Today almost all cities have public libraries. Japanese university and college libraries have also seen substantial improvements in technology, networking, and new library construction in recent decades. Economic growth also brought development of special libraries. User interest is now mainly directed toward the Internet and electronic resources and this has spurred library development of digital searching and storage.

The history of modern museums in Japan dates back to the time of the Meiji Restoration. The museums were initially set up to organize exhibitions for display of various articles. For this reason, the activities of the museums focused mainly on "organizing exhibitions" rather than building and management of collections. This characterized Japanese museums (in particular museums of fine art), curators, and museum specialists. Against this background, librarians, conservators, educators, and other specialists have been progressively staffed for individual sectors. Furthermore, reforms are underway for making collection databases, opening data to the public, and introducing the IAA system and third party management evaluation.

Archives in Japan are divided into three main groups: public archives, university archives, and private archives, including business archives. It was not until the late twentieth century that archival legislation, academic societies on archival studies, and training systems for experts engaged in the operation of archives were developed in Japan, and new development is still underway. Interrelationships among archival institutions are based on the decentralized administration system and there is no unified base or central management organization for implementing archival policies. Digitized archival materials are provided online on a large scale by the Japan Center for Asian Historical Records.

In Japan today, the fruits of the progress in information technology is becoming increasingly widespread among libraries, museums, and archives. The pace of digitization is remarkable, and development of digital libraries, digital archives, and other digital projects have become common. Under these circumstances, professionals in this field in Japan also recognize the need for links between museums, libraries, and archives (otherwise known as "MLA partnership"). Nationwide networks that include the principal institutions are already being formed by the curators of museums, libraries, and archives. There are now plans to go further in forming and consolidating MLA partnership as a reciprocal relationship that will embrace all of these

and transcend boundaries between different types of institutions. In our opinion, the main issue to be resolved before this can be realized, however, is the problem of who should take leadership. Japan's library sector should take the initiative to bring about cooperation and coordination. But the JLA, which would normally be expected to take the lead in the MLA partnership, does not have enough capacity to achieve this. The National Diet Library has its own institutional issues that prevent it from taking national leadership on this agenda. Resolving this issue is of immediate concern to everyone working in data storage and search services in Japan.

ACKNOWLEDGMENTS

We would like to express our appreciation to a librarian, Charles Laurier, librarian at Lakeland college in Tokyo.

Abstract

This entry describes the development and present situation (as of 2007) of information institutions and practices in Kazakhstan, primarily the histories and cultural roles of libraries, archives, and museums, and the education, status, and activities of information workers.

INTRODUCTION

This entry describes the historical development and current conditions of libraries, archives, and museums in Kazakhstan. Early institutions and practices in the region were Islamic, and later Russian imperial and Soviet influence is also still evident in educational philosophy, scientific practice, and institutional structure. Today institutions face the challenge to modernize and globalize information practices in a multiethnic, multilingual state.

Kazakhstan is in the middle of the Eurasian land mass (Fig. 1). Bounded by China to the east, Russia to the north and northwest, the Caspian Sea to the southwest, and Turkmenistan, Uzbekistan, and Kyrgyzstan to the south, it is the ninth largest country in the world (2.7 million km²). The desert, steppe, and mountain ecologies have supported nomadic pastoralists, trade cities of the Silk Road, and settled agriculturalists. At 15.3 million citizens, it is the least densely populated Central Asian state. The development of rich oil, gas, and mineral resources makes Kazakhstan the wealthiest Central Asian republic, second to Russia among the former Soviet republics.

History

By 1500 B.C.E. horse-herding nomads were inscribing petroglyphs at Tamgaly (Fig. 2). Several cultural traditions later marked the region's inhabitants: the Scythian or Saka presence from the eighth to the third centuries B. C.E., the spread of Islam from the seventh century C.E., the Mongol incursion in the thirteenth century, the Persian-influenced Timurid dynasty from the fourteenth century, the rise of the Turkic Uzbeks in the fifteenth century, and the entrance of Russia from the eighteenth century. The Muslim philosopher Al-Farabi (ca. 870–950) is said to have founded a library in his birthplace Otrar

that rivaled ancient Egypt's Alexandria. The Mongol forces of Chingiz (Genghis) Khan (ca. 1162–1227) later destroyed Otrar and other localities. Many of these places were rebuilt under Chingiz Khan's descendant Amur Timur (Tamerlane) (1336–1405), including the mausoleum of the Sufi poet Khoja Ahmed Yasavi (1106–1166) in Turkistan. In the fifteenth century the Kazakhs emerged as a distinct cultural and linguistic group from the Uzbek confederation of Timur's descendant Abu'l-Khayr Khan (ca. 1412–1468). The appellation *Kazakh* is most commonly translated as “free, independent.” Other proposed etymologies include from Old Turkic *qazgac*, “to gain”^[1] or from a Turkic term used to describe splinter groups.^[2] In the early seventeenth century the Kazakh khanate split into three competing *zhus* or hordes. External threats from Mongol Oirats and Dzungars in the eighteenth century led Kazakhs under Ablai Khan (1711–1781) to turn to China and Russia for recognition and protection.

By the nineteenth century the Russian Empire had established settlements across the north including Uralsk (Oral), Semipalatinsk (Semey), and Ust-Kamenogorsk (Oskemen) and a frontier outpost in the south, Fort Vernyi (Almaty). Colonizing Russians disrupted Islamic influence in the region, in part by establishing Russian-language libraries adjunct to their military installations in the region, which served increasing numbers of immigrating Slavs.^[3] Soviet-era historians describe this as a period of enlightenment when individuals such as Chokan Valikhanov (1835–1865) (descendant of Ablai Khan), Ibrai Altynsarin (1841–1889), and Abai Kunanbayev (1845–1904) (Fig. 3) aspired to spread the benefit of books and reading among Kazakh people. More recent histories note uprisings against the Russians during this time that suggest the beginnings of Kazakh nationalism.

Source: Adapted from *CIA World Factbook*, <https://www.cia.gov/library/publications/the-world-factbook/geos/kz.html>

Well into the nineteenth century Kazakhs were a people of oral tradition, and when imperial Russia required literacy from Kazakh elites it was in Russian.^[4] In 1918, the new Soviet state found Central Asians to be largely illiterate and early literacy campaigns focused on primary education—the Kazakh region reached acceptable levels of literacy in the 1930s.^[5] Russian was the main language and written Kazakh was converted from Arabic and Latin into a modified Cyrillic script. Authors who wrote on

Kazakh themes or in the Kazakh language were sometimes exiled or executed, including poet Saken Seyfullin (1894–1938) and linguist Akhmet Baytursynuly (1873–1938).

During the Soviet era of the twentieth century (1918–1991), the region became increasingly collectivized and urbanized. The Communist government required nomads to adopt more sedentary animal husbandry and industrialized methods of agriculture. Cities developed into centers

of economic and cultural life, supporting urban institutions such as schools, hospitals, libraries, museums, and book and newspaper publishers. When the single Turkistan Autonomous Soviet Socialist Republic proved difficult to administer, Central Asia was divided into smaller republics in 1923 and 1924, and boundaries were redrawn again several times. Immigrants came from other Soviet Republics as internal exiles, war refugees, or developers of virgin lands, and forced migrations of Koreans, Crimean Tatars, Germans, and others also populated the area so that by the 1960s ethnic Kazakhs had become a minority group.

Present Day

Kazakhstan was the last state to declare independence from the Soviet Union on December 16, 1991. The country is organized into 14 administrative units known as *oblasts*, plus the two city units Astana and Almaty, the present and past capitals. The government recognizes over 130 ethnicities in the country; 2006 figures estimate

9 million Kazakhs, 4 million Russians, 450,000 Ukrainians, 433,000 Uzbeks and 250,000 each of Uighurs, Tatars, and Germans. Religions include varieties of Islam (60%), Christianity (30%), and others such as Judaism, Hinduism, and Buddhism. The monetary unit is the tenge (KZT), valued at roughly 120 tenge to the U.S. dollar in September 2007. President Nursultan Nazarbayev has led the country since 1989 and may run for re-election indefinitely: recent legislation limits future presidents to two consecutive 5 year terms. Power is concentrated in the executive branch of the government, and national companies manage physical infrastructure and much of banking and industry. In an effort to enter the top 50 of the world's most competitive nations,^[6] President Nazarbayev has urged the development of an information society, supported by national research and development funds and manifested in projects such as the IT City recently established near Almaty.

The constitution identifies Kazakh as the state language (Article 7.1); authorizes government institutions to use Russian as equal to Kazakh (Article 7.2); and states that everyone should be able to enjoy their native language and culture (Article 19). Primary education may be in Kazakh or Russian, according to local circumstance, and in some urban areas parents may choose to enroll their children in either a Kazakh or Russian track. Government-mandated basic education curricula allot approximately 30% of teaching time to languages and literature.^[7] The majority of Kazakhstanis are at least bilingual, in Russian or Kazakh and a second language—Kazakh, Russian, or one of the minority native languages (e.g., Uighur, Ukrainian, Uzbek), and many are also proficient in other languages that are increasingly part of required school curricula (e.g., English, Mandarin, Korean, and Japanese).^[5,8] Literacy rates, which government statistics have reported as over 99% since independence, usually do not specify the language(s) in which literacy is assessed. The government's pursuit of a "sovereign (Kazakh) identity" may bring about a shift to the Latin alphabet for the Kazakh language within the next 15 years.^[9]

Publishing is a highly controlled activity in Kazakhstan, regulated by the AIC, the Agency of the Republic of Kazakhstan for Informatization and Communication.^[10] In 2006 the government recognized 314 sociopolitical, 1029 informational, 198 advertising, 172 science, 28 women's, 41 youth, 39 children's, and 37 religious media outlets in Kazakhstan. In 2007, 29 large book publishers reported operations in Kazakhstan, including specialty publishers of children's, legal, and reference works. At least in quantity, print publishing in Kazakhstan lags behind comparable EU states^[11] and the demand for Kazakh language materials in particular exceeds supply.^[12] As for booksellers, this entry's authors have observed that in cities, large chain-style bookstores are replacing book sales from corner kiosks and used dealers.

LIBRARY AND INFORMATION SCIENCE PROFESSIONS, SYSTEMS, AND SERVICES

History

Soviet-era libraries were organized in a hierarchy from the central research collections, down through regional university, college, institute and academy libraries, to public libraries in a variety of locations including factories, plants, trade unions, culture centers, and schools.^[13] Research libraries maintained broad and deep collections for the restricted use of scientists; university libraries provided approved knowledge to students; and public libraries worked toward universal literacy and the transfer of party policy and practical knowledge to the working classes.^[14] Following both Islamic and Russian-adopted European traditions, libraries emphasized preservation of key authoritative texts over dissemination of newer knowledge. Technologically, Soviet libraries fell behind their western counterparts beginning in the 1960s due to slow development of civilian telecommunications infrastructure and personal computers.^[15]

Legislation Concerning Libraries

Two government ministries supervise libraries. The Ministry of Culture and Information^[16] oversees more than 3500 national, regional and public libraries, and the Ministry of Education and Science^[17] is responsible for approximately 7500 school, university, professional, academic, and scientific-technical libraries. Some government agencies and research institutes maintain separate libraries, such as agriculture, health, and physics. From the Soviet era Kazakhstan continues the National Book Chamber that is responsible for state bibliographic control and cataloging, statistics on print publications, and ISBN and ISSN assignment.^[11]

Specific laws governing libraries and legal deposit have been drafted, but have not yet been adopted. In the meantime state libraries are regulated by standards approved in an order of the Ministry of Culture and Information from 2002.^[18] Legal deposit is regulated by the 1991 Soviet-era Law On Print Media and Other Mass Media Outlets, amended by the Kazakhstani parliament in 1995.^[11] Library legal deposit is entangled with regulations requiring deposit of all printed matter to “authorized agencies” that could be used to suspend publications and printers.^[19] Other relevant laws include On Informatization (2003), On Science (2001), On Mass Media (1999), On Culture (1996), the Patent Law (1999, amended 2007), On Trademarks, Service Marks, and Appellations Of Origin (1999), and On Copyright and Neighboring Rights (1996, amended 2004, 2005). The copyright law, which does not address fair use, has been analyzed as more attuned to Kazakhstan’s future international relations than its current

domestic situation,^[20] and as detrimental to information dissemination efforts in education and publishing.^[21] In practice, the unauthorized reproduction and translation of print and electronic works for nonprofit and commercial purposes is declining in situations where education about intellectual property issues is provided and laws are enforced.

National Library and Information Services

Kazakhstan has several national libraries. The predecessor of the oldest National Library^[22] was conceived by the Vernyi Municipal Council in 1910, and has had a series of prominent directors,^[23] from politician and statesman Uraz Dzhandosov (1908–1938) through Murat Auezov—Orientalist–philologist, diplomat, and descendant of Mukhtar Auezov (1897–1961), the author famous for his studies of the works of Abai. In 1931, this library became the State Public Library of the Kazakh SSR, with depository responsibility, and was renamed the National Library in 1991. In 2006 the library reported 280 employees and holdings of 5.8 million items. Collecting focuses on social studies, culture, art, literature, and linguistics. The library building, designed in 1971, is 30,000 m² and since 2006 is undergoing major renovation.

In 2004 the National Academic Library^[24] opened in Astana under the direction of R. Berdigaliyeva, formerly director of the National Library in Almaty. The Astana facility combines traditional library service with new communication and information technologies, as in a virtual reference service. A variety of electronic and some print resources are available.

A third national facility opened recently in the new Presidential Center of the Culture of the Republic of Kazakhstan^[25] in Astana. This library’s mission is to bring together materials on Kazakh history and culture from around the world, and to organize and preserve the materials for serious scholarship.^[26] The library is 15,000 m², with holdings of 700,000 items including the collections of the previous Saken Seyfullin Regional Universal Scientific Library and the first UN depository in Central Asia.

The National Libraries encourage the technological informatization of Kazakhstan’s public regional libraries in various ways. Multimedia collections are beginning; CD-ROM and Web-based resources are being introduced, as well as electronic document delivery, and a domestic automated library system, the Republican Automated Library Information System (RABIS) is underway. Development is progressing as quickly as budgets can provide infrastructure installation and sustained staff training.

Public Libraries

Public libraries are organized into a hierarchy from national to village libraries, and by categories of children’s, juvenile, special needs (blind and deaf), oblast

universal research, municipal, and rural libraries. The ministry estimates 9 million users annually, including 4 million reader accounts—public libraries operate on a subscription system in which a modest annual fee (300 tenge in 2006) secures privileges for facility use and borrowing. Service hours typically fall within the standard Monday to Friday 40 hr work week. Stacks may be open if space allows.

Public libraries continue to play an important role in supporting universal, lifelong education, and promoting national identity. Recent outreach programs have promoted the library as a center for ecological information and for village development. The “Library Capital” conference is held annually since 2001 at a regional library to advance regional innovation and develop local government support. Each conference produces a document of best policies and practices that is afterwards applied throughout the republican library network.

Kazakhstan also has a number of other institutions for general readers, sponsored by foreign embassies, multinational and nongovernmental organizations and cultural associations, and supported by membership fees, such as the British Council libraries.^[27] Library materials typically promote the language or purpose of the supporting agency. Such collections may close and open with economic and political changes—for example, a “new” American Corner at the Central Scientific Library, opened in 2006, reinvigorates a collection of books donated in the early 1990s.

Academic and Research Libraries

The Ministry of Education and Science^[17] exercises centralized control over all aspects of the educational process beginning from preschool. Higher education begins with undergraduate training or study at the 181 colleges and universities (51 public and 130 private) attended by nearly 1.3 million students in 2005–2006. In its education strategy for 2005–2010, the government is working out procedures for accreditation so as to harmonize the quality of grading with the terms of the Bologna process.^[28] In efforts to bring Kazakhstan into line with international standards, many universities are in transition from 5-year *diplom* to 4-year baccalaureate programs, and from highly structured program requirements to a more flexible credit system.^[29] Graduate departments exist in 72 universities and 70 research institutes, and were attended by 4700 postgraduates and 303 doctoral students in 2005. Graduate level education is also in flux, with Master’s and Ph.D. programs offered alongside *aspirantura* and *candidatskaya* degrees. The terminal Soviet degree, the *Doktor Nauk*, once paved the way to positions in one of the approximately 30 academies of sciences, the premiere research institutions in the Kazakh SSR. Since independence, foreign aid has increased the status of universities

and their teaching professors vis-à-vis research academies and their members.^[30,31]

Academic and research libraries are typically open only to members of their institutions (at national or oblast facilities, credentialed scholars) during the standard work week. Closed stacks and fee-for-service, on-site use of print and electronic resources are the norm. Electronic cataloging has been introduced, and institutions with large collections face generations of work to convert card catalogs, as well as the items they describe, to electronic formats.

Research libraries

The Central Scientific Library^[32] is the main research library for scientists and scholars in the country. (In Russian, “scientific research” connotes the entire range of scholarly activity, from poetry to physics.) Founded in Almaty in 1932 as the Kazakh affiliate library of the Academy of Sciences of the USSR, it currently holds over 5.3 million volumes in its main facility and 16 affiliate libraries throughout Almaty and the republic. Collections span the arts and sciences, including the largest foreign languages collection (850,000 items) in Central Asia. The main facility of 37,000 m² is undergoing a major renovation from 2006. Director K. Abugalieva manages a staff of about 300.

The Republican Scientific-Technical Library (RNTB),^[33] headquartered in Almaty, was created in 1960 to support scientists, engineers, innovators, and researchers. In 1966–1976 a centralized system of the country’s regional scientific-technical libraries was developed, which now includes several Almaty locations and 12 regional libraries. Combined holdings of 23 million items include patents, dissertations, and standards. The total staff of 447 is headed by General Director-RNTB Director K. Urmurzina. RNTB uses IRBIS, a mid-1990s Russian automated library system inspired by UNESCO’s CDS/ISIS package.^[34] O. Kvochkina, head of RNTB’s Center for the Development of Libraries, also manages the Information Consortium of Kazakhstan.^[35]

University libraries

The Scientific Library^[36] of Al-Farabi Kazakh National University (KazNU)^[37] supports the leading higher educational institution of the republic (annual enrollment: 15,000). Established in 1934, this largest university library in the country holds over 2 million items at various campus facilities and in 1962 was designated the scientific-methodical center for libraries of educational institutions.

The Scientific-Technical Library^[38] of the Kazakhstan National Technical University^[39] (annual enrollment: 12,000) was also created in 1934, with the 8500 volume collection of the Semipalatinsk Geological Technicum Library. It has become the most important university

Fig. 4 The KIMEP Library.
Source: Photograph by Leslie Champeny.

technical library for the Almaty area with 1.3 million current holdings. In recent years the library has been able to add facilities, collections, and computing capacity with the support of the U.S. Agency for International Development (USAID).

Notable among private universities is the new library at the Kazakhstan Institute of Management, Economics and Strategic Research (KIMEP)^[40] that was completed in 2006 (Fig. 4). KIMEP, an English-language university offering social science and business education to over 3000 students, has been fortunate to be able to combine its heritage as the former Communist High Party School with over a decade of strong international support to produce a four-floor facility with open stacks for 100,000 books and 7-days-a-week study space.

School Libraries

Public education is mandatory and free. Preschool for children aged 5 and 6 was recently reformed, and basic education is divided into three grade levels: 1–4, 5–9, and 10–11. School libraries are managed by an oblast administrator responsible for oversight of proper materials to support approved curricula throughout the region. The position of school librarian is a recognized degree specialty. Funding is at discretion of the school principal, and many schools encourage additional support from parents including the purchase of textbooks.

Special Libraries

Medicine and law (like library science) are undergraduate professional degrees. Law schools and law offices

maintain their own resource collections. Legislative decisions are first published in a government register, and commercial indexes can be purchased on CD or subscribed to online. The Ministry of Health^[41] information resources focus on pharmaceuticals, and medical schools maintain their own libraries. Business does not yet appear to support corporate libraries, although there is a keen appreciation of information as a competitive advantage and a marketable product. More common is for well-established libraries to be offered specialized resources in exchange for providing space and staff to maintain services—for example, the National Library in Almaty hosts a collection of oil and gas information resources funded by an international petroleum company.

Digital Library Collections and Services

Libraries are eager to possess digital technologies and collections. International support for digital library development since the mid-1990s is beginning to show results. For example, UNESCO's 2004 training in Greenstone digital library software enabled the Human Rights Digital Library launched in 2006 at the National Academic Library. Collections of locally produced electronic documents are beginning to appear online at some of the larger libraries, including digitized rare manuscripts and musical recordings.

Librarianship and Information Science as a Discipline and Profession

Considering the relatively recent development of mass literacy in Kazakh society, and the decades of Soviet censorship that followed, it becomes apparent why jobs like

Fig. 5 Kazakhstani librarians continuing their education.

Source: Photograph by Leslie Champeny.

journalist, publisher, and librarian might be low in security and status. The librarian (and wife of Lenin) Nadezhda Krupskaya (1869–1939) is a model who represents the essential role of libraries in education and nation building. Those within the profession recognize the erudition, technical expertise, and multilingual abilities required. It is difficult to attract individuals with this skills set to entry-level positions at low wages, and equally difficult to retain their services after they develop the skills on the job. Library-flavored information science hardly exists, although there are excellent mathematicians, linguists, computer scientists, and business information systems experts.

Regarding professional education, in 1934 the first Regional Kazakh Library College was formed, and the undergraduate degree in library science and bibliography is currently offered at three institutions. Required courses cover the history of the book, bibliographical theory and description, user issues, library management, collections (*fond*) and information resources, and automated library systems; specialized disciplines include documentation, networks, bibliography of Kazakhstan, standardization, information culture, and library marketing. In 2001 a postgraduate course on Librarianship, Bibliography Science, and Book-Science was developed and in 2004 a graduate program opened at a state university. Continuing education for professional librarians is available through the major libraries, often in conjunction with international development support organizations (Fig. 5). In 2000 the Eurasia Foundation and the Open Society Institute funded

the Centre for Professional Development of Library Workers at the RNTB.^[42]

As for professional associations, the Library Association of the Republic of Kazakhstan (LARK) (founded in 1997) brings together workers from a variety of libraries, offering occasional lectures and information on opportunities for participation in international organizations. National and scientific-technical libraries can join appropriate regional organizations. Major libraries regularly send participants to meetings sponsored by international organizations.

ARCHIVES AND ARCHIVAL SCIENCE

History

Archives were started by the Inner Bukeev horde around 1795. The present archival system derives from the USSR. In 1921 the first central archives was founded in Orenburg, the capital of Kazakhstan's predecessor state, the Kyrgyz Autonomous Socialist Republic. Aleksandr Mikhailov was its first director. The capital of Soviet Kazakhstan moved twice, to Kzyl Orda in the mid-1920s and to Almaty in 1929. Because of these moves, as well as several border realignments, some document collections remain in archives in Russia or other Central Asian countries, and others were lost. Nevertheless, Kazakhstan's archives include original documents from as early as 1733 on the khanates, on Kazakh accession to the Russian

empire, and on other state activity prior to and during the Soviet period.

Kazakhstan followed the usual Soviet model for state archives. In addition to the Central State Historical Archives, there was a Central State Archive of the October Revolution and Socialist Development (founded 1931), and these were combined in 1957 into the Central State Historical Archives of the Kazakh SSR. Regional archives were also opened during the 1920s. The 1940s–1950s brought improvements in archival processing and storage including a laboratory devoted to microfilming, preservation, and restoration, despite sporadic funding and support for training. Central archives for film, photographs and audio recordings, and for technical and scientific documents opened in 1974. By 1989 there were 20 oblast archives, including regional branches.

The Communist Party had its own parallel network of archives in Kazakhstan. Before the Revolution, the Central Committee of the Russian Social Democratic Party maintained collections in various cities. In 1920, the Russian Council of the People's Commissars (SNK) created a special body for the collection and study of documents relating to the October Revolution. A year later the Party created a special office to archive material in the *gubernia* (forerunner of the oblast). In 1943, Kazakhstan's central Party archive in Almaty became part of the Institute of the Party's History of the Central Committee. By 1980 there were 20 Party archives throughout Kazakhstan with around 200 employees.

Legislation Concerning Archives

By treaty Kazakhstan became the successor to the Kazakh SSR archives in 1992 but it did not pass any law regarding state archives until 1998. Between 1992 and 1998 a number of Ministry decisions and Presidential edicts ensured that the existing archives survived, though with minimal support. The 1998 law (with amendments from 2001) provides the legal framework for the current organization of Kazakhstan's archives. This law states that the items in the national archives collections are an inimitable part of the historical and cultural heritage of the people of Kazakhstan, and that the collections encompass all documents that have a bearing on the history and identity of the nation regardless of legal ownership. The law also created restricted archives for the security of the nation within the Ministry of Defense, the Interior Ministry's Committee of National Security, the Agency on Fighting Economic Crimes and Corruption, and the Agency for the Protection of the President. Most of the material in restricted archives is inaccessible but the Ministry of Defense archivists will process requests for information on persons who were politically repressed or regarding people in World War II. The 1998 law further authorizes the national archives to seek and retrieve originals or copies of items of national

significance to Kazakhstan from foreign archives, and the central- and oblast-level archives have retrieval agreements with Russian, Korean, German, Turkish, Egyptian, and other archives.

National Archive System

In 1992 the Communist Party archives became the Central State Archives of Recent History, and in 1994 the Presidential Archive. This archive remains in Almaty and is the most advanced in Kazakhstan with climate control and some electronic cataloging. The current director is V. Shtempel.

Archival activity is supervised by the Ministry of Culture and Information. On the national level the ministry's Committee of Information and Archives (originally the Committee for Managing Archives and Documentation) manages the National Center for Archeography and Source Identification; Central State Archive for Scientific and Technical Documentation; Central State Archives; Central State Archive of Film Documents and Audio Recordings; Science and Technical Center for Document Management and Archival Activity; State Repository Collection of Document Copies; and the National Archives of Kazakhstan. The current and fourteenth head of the Central Archives is B. Zhanaev.

Government archives are organized by *fond* (collection), *opis* (register), *delo* (file), and *list* (page). In 2003, the National Archives had approximately 13.6 million documents and was growing at a rate of half-a-million documents a year. The national archival collection included 1,090 fonds in the presidential archives, 144 fonds in the scientific-technical archives, 284,700 records in museums and libraries, and 10,900 audiovisual records.

Oblast and Municipal Archives

In 2006 Kazakhstan had 16 oblast-level departments of archives and documentation, 36 oblast filial archives, and 166 regional and municipal archives. Regional archives are subordinate to the national Committee of Information and Archives. Administratively, they are branches of the regional governments. The oblast archives include all media in one collection. They are tasked with being repositories of nationally important documents of local origin and inputting this information into Kazakhstan's unified document accounting system. All of these archives have published guides and aids to their collections; mount local exhibits of archival documents; and provide technical and organizational leadership in document retention to local organizations and government agencies. They are the repositories of employment and other business documents of the oblast.

Archival Work

All documents that have national value are part of the national archive system, no matter their origin, location, or format. Examples are legislation, construction project drafts, technological patent licensing, machine readable and audiovisual documentation, and historic and cultural documents. The state archives must maintain a catalog of this material, with the help of the sources of the items. The documents originating in private or other government agencies must be kept and cataloged for the national archival system. The Committee of Information and Archives has produced rules for the handling of documents and defining the length of retention. If a legal entity (e.g., corporation) ceases to exist, certain documents must be organized and delivered to the oblast or city archives (e.g., employment documents, records of board meetings).

The National Archives is actively pursuing document preservation and the retrospective conversion of paper documents into other media. The State Insured Collection of Document Copies of the National Archives Collection has prepared over 1.6 million frames of microfilm, restored over 12,000 pages of faded text and converted into digital format over 818 photographs, 172 films and 1,350 photographic documents.

In 2006 the government developed its 2007–2009 archival development plan. It announced that its archives would work to become ISO 15489-certified by the end of 2009. The plan notes that current conditions in some archives are not yet compliant with existing national requirements, due to lack of a single unified electronic information system and limitations of older infrastructure.

Kazakhstan initiated efforts in 2002 to develop electronic archives. The Presidential Archives became the first to introduce an electronic holding system and a program to digitize existing holdings. The archives' database shows partial holdings, and as of 2004 the archivists still operated the database for the client. Problems with the rate of digitization, storage, and integration of new document formats were reported in 2006. In the same year the government formed a working group towards creating an "electronic government" by 2009 that included archivists to examine issues regarding the introduction of a nationwide system of electronic archives.

Print and electronic publishing activity

Since 1987 the Center of Scientific and Technical Information on Document Handling and Archival Activity has published a national quarterly. The Central State and oblast-level archives publish periodically, including *The Archival Herald* (Karaganda Oblast, since 2000) and *The Archivist* (Kostenai Oblast, since 2002). An independent monthly covering document management and archives, *Deloproizvodstvo v Kazakhstane*, began publication in 2007. Under the auspices of UNESCO's HeritageNet program, several CDs of archival documents were produced,

including *Kazakhstani Chronicle* (2000), a short history of Kazakhstan from the National Library's collection of newspaper articles 1913–1937, and *The Electronic Archive of Kazakhstan* (2002), 168 pages of archival documents from the seventeenth and eighteenth centuries.

The Central State Archives Internet site^[43] published legislation and regulations pertaining to archives and their use, a list of the oblast-level archives and their publications and other basic information. Closed temporarily in June 2007 for lack of funding, the government's 2007–2009 plan includes a new or upgraded site. The Presidential Archives Web site^[44] includes contact information, a small history, description, and rules on the use of the collections, and its semiannual bulletin. Archive Web sites of Eastern Kazakhstan Oblast^[45] and Kostenai Oblast^[46] include full texts of the laws and regulations governing archives, and descriptions of the collections and services offered.

Access and Use

Access and use of the archives are guaranteed to all. The Committee of Information and Archives has created detailed rules for access. Documents judged to contain state or commercial secrets or that would violate the privacy of an individual have restricted access. The managers of individual archives may judge original documents as too fragile or valuable to be given to a researcher and may substitute copies.

Committee rules state that researchers should present an official letter from their sponsoring organization. University students should present a letter from the rector of their school asserting the necessity of the archival documents for the student's research. Independent researchers must prove their identity and complete an application form to the proper archive. Permission is typically valid for 1 year or one stay in Kazakhstan. A change in the area of research requires a reapplication. There is a daily limit on the number of registers that may be used and an annual limit on photocopying. Visitors are provided free consultation, have access to any automated catalogs, may bring in their own documents and avail themselves of a translator's services.

Archival Science as a Discipline and Profession

In 2007, the Kazakhstan Central State Archives Web site listed 12 colleges and universities that offer programs appropriate for work in archives, sometimes combined with document management programs. Working archivists must be certified periodically by the Committee for Information and Archives. Government-mandated continuing education is frequent, and has recently focused on compliance with the changing labor code and the administration of documentation transition to the Kazakh language.

Archivists may belong to the Society of Archivists of the Republic of Kazakhstan. Kazakhstan is also a member of international organizations on archives including the International Council of Archives, the International Federation of Information and Documentation, the International Association of Sound Archives, and the International Federation of Television Archives.

In sum, the role of documentation in Soviet society cannot be overstated, and made archiving an essential profession. However, the resulting “document explosion” has made the archivist’s task extremely difficult. The status of archiving as a profession also suffers from the Soviet reputation for altering documents. Similar to libraries, archives have difficulty attracting and retaining talented employees.

MUSEUMS AND MUSEOLOGY

The history of museums dates to 1832, when Vladimir Dal (1801–1872) (who would become Russia’s first lexicographer) was sent to the Russian military outpost at Orenburg. Dal took an interest in the nature and culture of the region and reportedly opened a museum of zoology and botany, and some of his collections now reside with the Central State Museum in Almaty. Today the Ministry of Culture and Information reports more than 150 museums throughout Kazakhstan, primarily regional, historical, and ethnographic, fine arts, and biographical memorial institutions; unique topics including mining and rice cultivation. The ministry estimates that 20,000 exhibits and events have been presented in recent years with an attendance of approximately 1 million.

National Museums

There are six national museums. The Central State Museum^[47] is one of the largest museums in Central Asia, with permanent and rotating exhibits on natural history and cultural heritage. The museum opened in 1931 in Almaty’s Cathedral in Panfilov Park, incorporating collections of the Cossak Army and the Republic Anti-religious Museums. In 1985 it moved to its current facility of 17,577 m², where it can display about one-tenth of its 200,000 item collections. A journal *Kazakhstan Muzeileri* (“Kazakhstan Museums”) has been published since 2002.

The Kasteyev Arts Museum^[48] was named for the first major national artist Abylkhon Kasteyev (1904–1973) in 1984. The museum originally opened as the National Art Gallery in Almaty in 1935 with an exhibit celebrating 15 years of the Kazakh SSR. In 1936 the State Tretyakov Gallery and the A. Pushkin State Museum of Fine Arts in Moscow donated approximately 200 works. In 1939 the gallery was named after the Ukrainian writer Shevchenko on the 125th anniversary of his birth. In 1976 the gallery and the Museum of Applied Art moved to a new building

of 19,400 m² with ample storage space, photo laboratory, large exposition halls, and climate control. It owns about 22,000 Kazakh, Russian, European, and Asian fine art showpieces including paintings, graphic works, sculptures of popular arts and theatre, and decorative art.

Of special interest to librarians, the Republican Book Museum was opened in Almaty in 1978. It has six halls for exhibitions of the history of Kazakh writing and book printing as well as modern publications in Kazakhstan. Holdings include 5,123 rare original manuscripts, ancient books and drawings, and 45,000 other books, periodicals, booklets, emblems, and charts (Fig. 6).

The State Museum of Popular Musical Instruments was created in 1980 in a beautiful nineteenth-century wooden building in Almaty’s central park. The collection displays instruments from Kazakhstan and around the world including the personal *dombras* (a long necked, two-stringed instrument similar to a lute) of famous Kazakh poets and composers such as Abai.

The State Gold and Precious Metals Museum was founded in 1990 as the main repository of Kazakh jewelry from the earliest time up to present. It annually replenishes its collection with unique showpieces.

The newly established State Museum of Archeology and Ethnography^[49] is in the Presidential Centre in Astana. This museum is charged with the material and technical, managerial, scientific-methodical, and financial backing of studies of the country’s national cultural heritage and current development. Its collections include the Berelskaya and Buzuk archeological items, and gifts given to the Head of State.

Other Museums, Galleries, Zoos, and Preserves

Each oblast has a museum that includes science and natural history-themed exhibits, and several academies of the natural and physical sciences operate small museums. Notable is the Geology Museum in Almaty, which offers an interactive computer show demonstrating different geological processes. KazNU reports museums for its departments of paleology, archeology, and biology. In Semipalatinsk, site of former Soviet nuclear testing grounds, the state medical academy maintains a teaching collection of malformed fetuses that is said to be unforgettable.^[50]

Oblast museums present exhibits of regional history or ethnography. In addition to the World Heritage sites of Tamgaly and the Yasavi mausoleum, the Ministry of Culture and Information supports several other historical and cultural reserves, and large-scale digs at 32 sites of ancient settlements, burial grounds, and tumuli were performed in 2005. Biographical memorial museums are numerous, as are monuments, statues, and commemorative plaques on buildings associated with prominent persons.

Many oblasts also operate art museums for their regions, and there are numerous art galleries in urban centers. Four zoos (and three circuses) operate in

Kazakhstan. Nine national nature preserves protect over 70 plant and 129 animal endangered species.

Museology as a Discipline and Profession

Museums are valued primarily as cultural and historical centers, and are responsible for the organization of scientific research to elucidate and preserve Kazakhstan's national heritage. Archaeological and ethnographic work is especially important given the relatively recent development of written history. Perhaps even more than libraries, museums have become a tool for promoting national identity locally and internationally, as in the organization of exhibitions such as *Of Gold and Grass: Nomads of Kazakhstan*,^[51] which recently toured the U.S. Professionals in the discipline may be found in research and consulting positions in museums, historical and cultural centers, specialized schools and colleges, governmental management bodies, and tourist organizations.

Regarding education for curators and museum administrators, museology was a certified undergraduate degree in the USSR, usually offered from a department of archaeology or history. Current educational paths to museum work are the designated specialties Culture Studies, Archaeology and Ethnic Studies, and Museums and Preservations of Artifacts, offered at three state universities. The curriculum includes organization of museums, conservation and reconstruction of historical artifacts and culture, regional studies and research, organization of regional studies museums in secondary schools and colleges, expertise and consultation on culture in government, and creation of historical sites tourist routes.

Regarding professional associations, the National Committee of the International Council of Museums assists the country's leading museums to enter into cooperation with

international institutions such as the British Museum, Russian State Library, and Hamburg Ethnographic Museum.

CONCLUSION: TOWARDS THE FUTURE

Kazakhstani librarians of a certain age often reminisce about the old days of economic and job security, when they were part of the largest network of information institutions on earth, and the sharing of knowledge among the republics was well regulated and reliable. With the departure of Russian economic and administrative support, interorganizational cooperation declined for a time as each institution struggled to maintain its own resources. With the encouragement and support of the international community, information professionals are beginning to rebuild the network of relationships that will be required to support information sharing practices such as interlibrary loan.

Ambivalence remains about how to build on the Soviet legacy while at the same time acknowledging, and then solving its problems. The call to forge a new national identity is one proposed solution, and many information institutions have responded, as in recent library projects *Til Oneri* ("Language is the foundation of everything"), *Shanyrak* (history, cultural traditions, and customs), and *Atamura* (the revival and preservation of national musical heritage). Language issues already affect the daily decisions of information workers from catalogers to programmers and publishers, and policy changes will further complicate decision making at all stages of the information cycle, for example, regarding production formats, organizational schemes, and selection of items for preservation. The focus on informatization is another solution, perhaps less politically charged at present, but also more expensive.

Institutions will have to upgrade infrastructure, import technologies, retrain staff, and improve organizational operation to participate fully in the global information society. Given Kazakhstan's regional economic dominance, it is to be hoped that the political will exists to implement the necessary changes.

ACKNOWLEDGMENTS

We are deeply grateful to the staffs of the ministries and institutions described in this entry, especially A. Yusupova of the Central Scientific Library. We also appreciate the suggestions of two anonymous reviewers, which we have incorporated wherever possible. Special thanks to our colleagues at KIMEP, whose collective wisdom spans more than 40 years in information institutions across the former Soviet space.

APPENDIX 1

Table A.1 Timeline

Century	Event	Year
15 th B.C.E.	Horse-herding nomads at Tamgaly	
8 th –3 rd	Scythian Saka in region	
B.C.E.		
8 th C.E.	Islam introduced	
9 th –10 th	Al-Farabi (870–950) builds library in Otrar	
12 th	Khoja Ahmed Yasavi (1106–1166) retires to underground cell in Turkistan	ca.1163
13 th	Chingiz Khan (1162–1227) sacks Otrar	1219
15 th	Amur Timur (1336–1405) dies in Otrar; Kazakh khanate later emerges from his descendants' rule	
17 th	Kazakh khanate splits into three <i>zhuz</i>	
18 th	Ablai Khan (1711–1781) allies with Russia against Mongol threats	
19 th	Fort Vernyi established	1854
	Abai Kunanbayev (1845–1904) writes Kazakh poetry	
20 th	Kazakhs protest conscription into Russian army	1916
	Bolshevik Party takes control of Kazakh <i>Alash Orda</i>	1919
	Turkistan Autonomous SSR split into Central Asian republics	1923–1924
	Kazakhstan becomes full-fledged Soviet Socialist Republic	1936
	Great Patriotic War; Stalin deports undesirables to region	1941–1945
	Soviet nuclear tests begin near Semipalatinsk	1949
	Kruschev declares virgin lands campaign	1954
	First manned space launch from Baykonur	1961
	Republic of Kazakhstan becomes independent state	1991

Abstract

This entry traces the evolution, development, and growth of information systems in Kenya, especially noting the importance of Information Communication Technology in propelling economic development. The authors provide a historical overview of libraries, archives, and museums, outlining patterns and trends through precolonial to post independence. Topics covered include: national, public, academic, special, and school libraries; Kenya National Archives and Documentation services and the regional record centers; National Museums of Kenya, regional museums; and sites and monuments of national and international importance. The legal framework upon which these institutions were established and operate is highlighted. The entry also identifies some key personalities who have made an impact in the fields of librarianship, archival services, and museology in Kenya and discusses the role of professional associations in the development and growth of these institutions.

INTRODUCTION

Kenya is an Eastern African country that is bordered by Ethiopia to the north, Somalia to the northeast, and Sudan to the northwest, Uganda to the west, and Tanzania to the south, with the Indian Ocean providing the southeast border. The Equator runs through the center of the country. The climate varies from the humid tropical areas in the coastal region to a cool Mediterranean climate in the highlands in the Southwest. The majority of the terrain is made up of low plains covering about three-fourths of the country. Kenya boasts of a spectacular variety of wildlife. These include elephants, lions, giraffes, zebras, buffalos, and other wild beasts, which attract tourists to Kenya (Fig. 1).

Kenya is comprised of people of all races and religions, and includes over 42 different tribes. A large percentage of the population lives in the rural areas in small settlements where they raise crops and livestock for a living. Many of these farmers also hold part-time jobs to add to their income. However, each year, many rural Kenyans move to towns to find jobs. Most of the urban population work in factories, stores, supermarkets, government

offices, or carry out business. Kenyans, who move to cities, must adjust to the fast pace of life in the cities and regular work schedules.

The British colonial government ruled Kenya from 1895 until the country attained independence in 1963. During this time they influenced political, social, economic, and cultural life in Kenya. However since independence, the indigenous leaders have emphasized the African heritage of the nation. Politically, Kenya is a republic which adopted its constitution in 1963. The constitution grants its people the fundamental human rights such as freedom of speech, freedom of expression, freedom of association, intellectual freedom, and religion. Kenya is headed by a president elected by the people through democratic elections every 5 years.

While initially Kenyan children were not required by law to attend schools, the current trends dictate that the government be more forceful on school attendance. Although educational opportunities have continued to expand, the demand for education at all levels has outstripped the available educational institutions. Kenya has over 13,000 primary schools, over 4000 secondary schools, several middle-level colleges, 7 public universities,

Fig. 1 Map of Kenya.

Source: CIA World Factbook. <https://www.cia.gov/library/publications/the-world-factbook/geos/ke.html>.

and over 10 private universities. As the literacy levels grow, albeit slowly, the need for information in the country has also grown.

The field of library and information is relatively young in the country. Most of the supporting legislation for libraries, archives, and museums were enacted in the 1960s. However there has been a significant growth in the number of libraries and information centers in the past decade and this can in part be attributed to the importance attached to education by individuals and the government. There has been an increase in the number of universities, middle-level colleges and schools. The publishing and book industry is still not fully developed and the reading culture in the country struggles to flourish. If well utilized, the National Archives should therefore become a very important basis for national planning and development. The Archives provides key linkages with the past, present, and future of Kenya.

LIBRARIES

Historical Background

The first library known in Kenya was established in 1887 by the European missionaries at Frere town near Mombasa. The establishment of modern libraries in Kenya can be traced to the early part of 1900s. At that time the creation of libraries was closely linked with the establishment of the British colonial rule and the subsequent arrival

in Kenya of European settlers and Indian traders. In an effort to propel economic development in the newly colonized areas, the colonial government identified the need to have a literate society. Although the history of libraries in Kenya cannot be divorced from the establishment of colonial rule and subsequent settlement of Europeans and Indian traders, library development is also closely linked to the growing political awareness of Africans following World War II. The war awakened a spirit of nationalism that preceded the agitation for self-government by patriotic Africans. After World War II Africans realized that their development lay in the European type of education which in turn required access to information.

The libraries that existed before 1945 were mainly set up to serve the interest of the white settlers and the Indian traders. The literacy level among the foreigners was higher than that of the indigenous Kenyans. This entry traces development of libraries and the growth of library profession in Kenya from precolonial period to date. The history of libraries in Kenya can be approached from three historical periods namely: precolonial, colonial, and postcolonial.

Precolonial period: During this period, there were no records of libraries existing in Kenya. This was mainly due to the fact that information was passed from one person to the other through oral traditions and art. These practices inhibited the growth of libraries. The only library on record during this period is said to have existed at Kilwa on the east coast and it served a small literate class of the community.

Colonial period: This is the period when missionaries began to appear in the East coast of Africa and set up a mission at Frere town. In 1887 they established a small library which was meant to be used by the new converts. However, in 1902 the *East African Standard* newspaper, which had been established by Mr. Jeevanjee, set up a news library which stocked reference books and manuscripts for use by the staff.

The High Court of Kenya Library was also established in Mombasa in 1902, but it moved its headquarters to Nairobi in 1905. It had a rich collection of reading materials on law. Later in 1935, a new building was completed in Nairobi which to date houses an important library that serves the judges of the High Court, magistrates, and advocates.

Other libraries established between 1910 and 1932 included Kenya National Assembly library and National Museum library in 1910, and the National public health library (now located at Kenyatta National Hospital) in 1911. The Attorney General's library was established in 1914 and Kenya Agricultural Research Institute library in 1927.

Library development followed racial patterns prevailing at that time. In 1903 that the philanthropic Asians founded the Seif Bin Salim public library in Mombasa. The collection, which was biased toward

Indian literature, was later acquired by Kenya National Library Service (KNLS) in 1975. In 1928, Lady Macmillan established a lending library for the white settlers in Nairobi. This library, which was named in memory of her husband, opened its doors in 1931. The Desai Memorial library was established in 1942 by the Indians providing the third public library in Kenya. Nevertheless, none of the established public libraries served African interests.

It was during this period that the colonial government realized the importance of ensuring that the colony was financially self-sufficient. Which meant the involvement of the Africans in the governance of the colony and this required that Africans be educated and be provided with the relevant information resources.

As a result of this that two kinds of libraries developed. First were special libraries to assist in exploiting natural resources of the colony. These included the Departments of Forestry and Agriculture libraries established in 1905 and 1907, respectively, and the National Assembly Library formed immediately after the first sitting of the Kenya Legislative Council in 1907. The second were public libraries including the Seif Bin Salim, Desai Memorial, and the Macmillan Memorial library. In 1948 Elspeth Huxley proposed the establishment of the East African Literature Bureau to produce and distribute literature to African libraries.

After independence: The 1960s were a turning point in the development of libraries in Kenya. The Macmillan Library was handed over to Nairobi city council and opened to all Kenyans. It became the first ever free and open public library in Kenya. Following the recommendation by the East African Library Association and by the British council library consultant, Sydney Hockey, the parliament enacted the Kenya National Library Service Act in 1965 (Chapter 225), of the laws of Kenya. The KNLS became operational in 1967 inheriting the resources and programs of the East African Literature Bureau.

Several government departments and private companies have continued to maintain libraries to support their ministerial and organizational programs. The desire by the government to embrace information in development planning saw the establishment of District Information Documentation Centers (DIDCs) in all districts headquarters. As per District focus circular 1/86 and Provincial Administration circular Ref. OP 16/174/11/23 of September 1984. The objectives of the DIDCs were to provide information to the District planning unit, District Development committees, individuals, and organizations involved in planning; collect and preserve the local statistics; support the planning, monitoring, and evaluation of development projects in the districts; strengthen the district capacity in the management of its activities. However accessing information is still constrained by the Official Secrets Act.

Legislation

Library and information service in Kenya is influenced by several legislations. Some of these laws were enacted during the colonial period while others were passed after independence. These laws have undergone several revisions to cope with changing trends in the field. These include the following:

Books and Newspapers Act (Chapter 111): This legislation can be traced back to 1906 and has undergone amendments in 1960, 1962, 1980, 1987, and 2002. This act serves as the legal deposit law of Kenya. The Act provides for comprehensive collection of all information materials produced in Kenya to enable proper bibliographic control and preparation of National bibliography.

Public Archives Act (Chapter 19): The Public Archives Act was established in 1965 and later revised in 1990 to become the Public Archives and Documentation Service Act. The purpose of the act is to establish the National Archives as a public archive and provide for the preservation of public archives and records.

KNLS Board Act (Chapter 225): This Act was enacted in 1965 and revised in 1969, 1970, 1984, 1988, and 2008. Through this Act, the KNLS board was formed and given the responsibility to “promote, establish, equip, manage, maintain, and develop libraries in Kenya as a national library service.” This Act empowers the board to advise the government, local authorities, and private sector on all matters regarding library development.

Science and Technology Act (Chapter 250): This law was enacted in 1977 and was revised in 1979, 1980, 1986, and 2000. The purpose of the Act is to promote scientific research and technological development in Kenya. Through this act, a mechanism was established to ensure that all matters of scientific and technological activities were available to the government. National Council of Science and Technology, which coordinates activities of all major research programs, was a product of this Act.

Industrial Property Act (Chapter 509): This Act was enacted in 1989. The goal of the act is to promote inventions and innovative activities in order to facilitate acquisition of technology through models and industrial designs. It also aims at protecting intellectual property through patenting.

Copyright Act (Chapter 130): This Act was established in 1966 and amended in 1989. It makes provision for copyright in literary artistic works, audiovisual works, sound recordings, broadcast, and for connected purposes.

The legislation discussed above covers the entire information field, from innovation and production (Copyright Law, Science and Technology, and Industrial property Act), to accessibility (Books and Newspapers Act, and Public Archives Act), to establishing and developing libraries (KNLS Act). The government of Kenya recognizes the need to develop an Information Communication Technology (ICT) legal framework that will act as a

catalyst for responsiveness and growth in the ICT sector for the benefit of all Kenyans.

Types of Libraries

National library

KNLS serves a dual role of public and national library. The National Library division was established in 1980 in recognition of the need for bibliographic control in Kenya. Some of the services provided include:

- Production of Kenya National Bibliography, Kenya Periodical Directory
- Legal depository center
- Centre for World Bank, UN publications, and IMF collections
- Issuance of International Standard Book Number to Kenyan publishers
- Interlibrary programs
- Rare collections (manuscripts and books out of print with research value)
- Online databases
- Government publications
- Africana and Kenyan publications

Public libraries

Libraries that provide public library service in Kenya include KNLS, Macmillan Library, and several cultural centers (embassy-sponsored libraries). The major public library service provider is KNLS, which has established 54 branches countrywide by 2008. Thirty-nine of these are community-based libraries developed in partnership with the local communities. The Macmillan library has four branches which are run by the city council of Nairobi.

Various embassies have cultural centers which are opened to the public, e.g., the American Cultural Centre, the Iran Library, and the British Council Library, among others.

Fig. 2 Camel library.

The KNLS has a wide network of libraries covering all the eight provinces in the country. Services provided include:

- Adult and junior lending.
- Advisory library services.
- Bulk lending of books to lending institutions.
- Technical assistance on library development to interested government and private institutions.
- Internet service in some of the branch libraries.
- Interlibrary lending, community information services, which include HIV/AIDS information service.
- Repackaging indigenous information.
- Service to the visually challenged persons.
- User education and outreach services including motorized (four mobile trucks and several motor bikes) and nonmotorized mobile library service (donkey and camel), book box service, and cupboard library service in schools (Figs. 2 and 3).
- The library also offers special services to children such as story telling, reading, and writing competitions, games, drama, and cultural activities among others.

Fig. 3 Donkey library.

Academic libraries

Academic libraries include university and college libraries. The demand for higher education in Kenya has resulted in the proliferation of institutions of higher learning. Currently, Kenya has over seven public universities with well-equipped libraries in the main campuses and in colleges spread in various parts of the country. These include Nairobi University, Kenyatta University, Jomo Kenyatta University of Agricultural Technology, Moi University, Egerton University, Maseno University, and Masinde Muliro University of Science and Technology. There are several private universities with sizeable libraries; among these are Baraton University, Daystar University, United States International University, Kenya Methodist University, Kabarak University, Kiriri Women University, and African Nazarene University among others.

The Kenya Commission for Higher Education requires all universities to establish a library managed by professionals before being awarded a charter. Universities therefore place libraries high in their development priorities. Many middle-level colleges and institutes offering certificate and diploma courses have continued to maintain admirable libraries to support their academic programs (Fig. 4).

Specialized research libraries

Research libraries have been developed in Kenya to support scholarly research in various fields. The oldest being Kenya Forestry research library, Kenya Agricultural Research Institute, an agri-based research institution, the high court library and Ministry of Agriculture library established in the 1900s. Others include:

- International Livestock Research Institute, which undertakes research on animal diseases.

- The Kenya Medical Research Institute, a human diseases research center.
- Kenya Industrial Research Development Institute.
- Kenya Institute of Public Policy Research Analysis, African Medical Research Foundation.

Other major centers for specialized research include international missions such as World Bank, UNESCO, UNICEF, UNEP, WHO, Bakhita documentation center, and Nongovernmental organizations resource and information centers among others. The Government Reference library housed at the Kenya National Archives and Documentation Service (KNA&DS) and the Museum library also serve as research libraries.

Other special libraries

Many businesses and public organizations such as hospitals, research laboratories, law firms, government departments and agencies maintain their own libraries for the use of their employees in doing specialized research related to their work. These libraries may or may not be accessible to members of the public. Some of these libraries in Kenya include the Central Bank of Kenya Library, Unilever library, Capital Market Authority library, National Assembly library, Kenya Bureaus of Standards, and Kenya National Bureau of Statistics. In addition, the Kenya Broadcasting Corporation has the richest collection of Audio-Visual Material of which a majority are gramophone records in East Africa. Most government departments and agencies also have libraries. Government libraries vary from ministry to ministry in terms of size, budgets, and personnel. While many ministries provide generous library support, others provide lukewarm support. For example, the ministries of agriculture, health, and planning have supported their libraries very well. However, inadequate government schemes of service and the lack of political goodwill from the political leadership have led to mass exodus of the professional librarians

Fig. 4 Margaret Thatcher library, Moi University.
Source: <http://www.mu.ac.ke>.

from many government libraries to better paying institutions especially the private sector libraries.

School libraries

Although some public and private primary and secondary schools have functional libraries, most public schools do not have adequate libraries. Only a handful of public schools can afford to employ professional librarians. Nevertheless, well-stocked school libraries are common features of private schools. These libraries also offer computer facilities for their learners. They remain accessible to the elite population who are able to afford the high tuition fee required. High performing secondary schools maintain well-equipped libraries. Mangu high school, Alliance girls and boy's high schools, Starehe boys and girl's centers, and Precious Blood School are good examples. Several have also employed qualified librarians to facilitate provision of efficient and effective library service to the school community.

With the introduction of Free Primary Education by the government in 2003 and free secondary education in 2008, respectively, public schools now receive a book budget. This might be a starting point toward school library development in both public primary and secondary schools in Kenya.

Education for Library and Information Science (LIS)

The need for trained manpower in Kenya can be traced to the 1950s when the Royal Technical College (now Nairobi University) was established. The college provided employees with in-service training in basic library skills. Later, the City and Guilds (a United Kingdom-based correspondence education program) started offering library courses through correspondence. These courses led to the award of certificates in librarianship. Library employees were encouraged to take these British correspondence courses organized by the Library Association of the United Kingdom. As libraries in East Africa developed, it became apparent that highly trained personnel at the senior professional levels were needed. In 1964, therefore, the East African School of Librarianship was established as a regional school located at the Makerere University in Uganda. The school offered non-professional library assistant courses. However, the curricula for the library training have changed tremendously over time.

In 1971, the United Nations Educational, Scientific, and Cultural Organization (UNESCO) developed the concept of harmonization as a basis for the training of information professionals. In the same year, the Kenya Library Association (KLA) appointed an education subcommittee to study the need for manpower in LISs in Kenya. In 1973, KLA facilitated the establishment of certificate programs in library and records management at the Kenya

Polytechnic. This training began in 1974 through a partnership of the UNESCO and the KLA. This was a 1-year certificate course which ran for 3 years. Prior to this, the only institution that had the mandate to offer library education was the East African School of Librarianship at Makerere University in Uganda. It offered nonprofessional library assistant certificate and much later diploma and postgraduate courses.

Training in LIS in Kenya is presently in various levels namely certificate, diploma, higher national diploma, undergraduate degree, and postgraduate (Master's and Doctorate) degree.

Certificate and diploma: These are accredited by

- National polytechnics—Kenya Polytechnic University college, Mombasa Polytechnic and Eldoret Polytechnic.
- Technical training institutes—Kenya Technical Training College, Railway training Institute, Sigalagala training Institute, Siaya Institute of Technology, among others.
- Private colleges—Kenya School of Professional Studies, Nairobi North college, Technical Institute of Management, among others.
- Universities—Nairobi University, Egerton University.

Undergraduate and postgraduate degree

- Moi University was the pioneer in the establishment of undergraduate training in LIS in Kenya in 1988.
- Kenyatta University.
- Kenya Methodist University.
- Egerton University.

Professional Associations

Kenya Library Association remains the single professional body that advocates for library professional standards in Kenya. It is a neutral professional association whose origin dates back to 1956 when the East African Library Association was formed. It draws its membership from all stakeholders in the field of information including librarians, documentalists, archivists, information specialists, record managers, and other interested persons.

In 1971, the Standing Conference of African University Librarians of East African met in Addis Ababa where UNESCO developed the concept of harmonization as a basis for training of information professionals (UNESCO, 1994, 2). KLA has continued to agitate for professional standardization and is heavily involved in all matters of library development and participates in forums where library education curriculum is being discussed.

It collaborates and partners with other international bodies for the benefit of its members. It is a member of International Federation of Library Association (IFLA) and Commonwealth Libraries Association (COMLA).

KLA major achievements are

- Hosting IFLA conference in 1984. This was the first time for IFLA conference to be held on the African soil and was attended by over 2000 delegates.
- Holding successful annual conferences over the years.
- Hosting COMLA and International Association of Agricultural Librarians and Documentalists conferences in 1983.
- Hosting Standing Conference of East and Southern African Librarians conference in 1998.
- Setting up a Web site through the assistance of International Network for Availability of Scientific Publications.
- Promoting reading culture through Children Reading Tents where it targets marginalized communities, peri-urban poor, slums, and people of low economic status.

In 2006 KLA celebrated a Silver Jubilee where personnel in library and information profession were recognized and given awards. These were

- Ralph Opondo—the first African city librarian in Kenya.
- Nathan Fedha—the first African chief archivist in Kenya.
- John Ndegwa—the first professional in LIS and the first university librarian in Kenya.
- Dr. Wanja Thairu—the first female Ph.D. in LIS in Kenya.
- Professor Ojiambo—the first male Ph.D. in LIS in Kenya.
- Jacinta Were—the first lady chairperson of KLA and member of International Federation of Library Associations and Institutions Board.
- Ruth Thomas—pioneer indexer and committed supporter of KLA.
- Jafred Musisi—a committed supporter of KLA who successfully lobbied to bring the first IFLA conference to Kenya (the first IFLA meeting in Africa).
- Late William Umbima—longest serving editor of KLA.
- Ann-Marie Kinara—pioneer documentalist in agricultural information in Kenya.
- Late Francis Otieno Pala—first chief librarian in KNLS.

KENYA NATIONAL ARCHIVES AND DOCUMENTATION SERVICE

“A nation without a past is lost and a people without a past is a people without a soul”—*Sir Seretse Khama (1980)*

Archives serve not only contemporary (often transient) needs but also the possible needs of researchers in the far distant future. They preserve the past to enrich the future.

Preserving the past, documenting heritage, and making it accessible to the public are the core function of the KNA&DS, which is a department within the office of the Vice President and Ministry of State for National Heritage and Culture.

Historical Background

Archives service in Kenya is a relatively recent development. Throughout the colonial era, which lasted from 1895 to 1963, there was no major effort on the part of colonial administration to preserve public records in Kenya. Between 1903 and 1948, these records were vulnerable to climate and theft owing to the quality of accommodation and storage then available—i.e., early colonial offices buildings were of corrugated iron and wood, which offered neither protection nor security. Many government officials were more concerned with destruction of records that appeared to hinder their work by clogging and congesting registries; such “unneeded” records could conveniently provide scratch paper. Apart from accidental destruction of public records, it is possible that there was unauthorized massive destruction contrary to official local and Colonial Office instructions. In 1910, Governor Percy Giroudi stressed the importance of preservation of public records for posterity by issuing a *Confidential Memoranda* on local official instructions on the destruction to *Provincial and District Commissioners*.

Fires also accounted for some of the destruction of colonial records in Kenya. For example, in September 1905, a fire broke out and destroyed some Government offices and Indian shops in Nairobi. The fire of September 1939 is another case, which involved a fire that burned down government facilities. The 1939 fire mysteriously broke out at night and destroyed the Government Secretariat Offices on the site presently occupied by the Prisons Headquarters in Nairobi. This unfortunate event had very disastrous effects on the records of the Central Government, especially those relating to the earlier days of colonization of Kenya by Britain. Fortunately the government was able to function through the generous cooperation of members of the public and other government departments. As Sir Walter Harragin, the then Acting Governor, admitted in the Legislative Council of November 14, 1939 in the Legislative Council Debate:

Since the war broke out, the government has had to cope with many and difficult problems. Its task has not been made easier by the fire at the old secretariat which resulted in the loss of the many valuable government records as well as most, though not all of the current files. The Secretary has however, been able to carry on reasonably efficiently, thanks to the cooperation of other government departments and of the members of the general public in supplying copies of correspondence with Government.

Following this calamity, no attempt was made to develop some “new records,” which could conveniently supplement the partially destroyed archives. Furthermore, the administration persistently showed the same lack of concern as before. The continued unauthorized destruction of public records arose from sheer neglect; in fact such records had been allowed to deteriorate to the point where massive destruction was inevitable. In some instances, the shortage of paper in district offices resulted in earlier records being sacrificed. One case in point occurred on June 8, 1948 when the District Commissioner, Kitui petitioned the Provincial Commissioner, Central Province for permission to use earlier files for preparing rough drafts, adding that he would salvage file covers and fasteners for future use. But surely, saving file covers and fasteners at the expense of public records was absolutely indefensible.

Despite the setbacks described above, as early as 1948 there was clearly widespread concern and dismay among the highest echelons of the colonial administration in the East African territories (Kenya, Uganda, and Tanganyika) over the haphazard accumulation of public records and their inevitable fate if they were not properly cared for.

In the three territories, it had become apparent that overcrowded conditions were creating a pressing need for more storage. Construction of accommodation for public records would not, in the long run, provide an adequate solution. Meanwhile, the uncontrolled destruction of documents had become the inevitable option taken in the absence of a suitable archival agency to which public records could be transferred. With this realization in mind, the Governors of Uganda, Kenya, and Tanganyika and the Administrator of the newly created East African High Commission embarked on high-level discussions aimed at finding a common solution to the preservation of the public records in their respective territorial jurisdictions. This process began in March 1948, when the Governor of Uganda Sir John Hall, wrote to the Governor of Kenya proposing the establishment of an archive service, either as an offshoot of the Central African Archives Service (which had been established in Southern Rhodesia) or as a common service within the auspices of the East African High Commission.

However this recommendation was not immediately implemented due to procrastination and long bureaucratic delays within the service. Finally in May 1952, the Deputy Chief Secretary, C.H. Hartwell, issued a proposal entitled “Accommodation, Equipment, and Staff for Central Government Archives in the New Secretariat.” In this document, he reviewed the progress made in the preservation of public records since the 1939 Secretariat fire. Hartwell asserted that following this fire, the problem of keeping closed files had not become acute. He warned that it would become a major problem within a few years unless early arrangements were made to address these issues. The thrust of Hartwell’s proposal was focused on the accommodation of public records in Nairobi. He was much less

concerned with preservation of those records in Provincial and District offices where they were stored in appalling accommodation. At a later meeting which was held on June 18, 1952, Bingley, the then government archivist, confirmed that “approximately 16,000 ft² was reserved for archives.”

Following the June meeting, the Chief Secretary issued a circular to all heads of departments, first, informing them of government decision to establish an archives service. Secondly, inviting the Heads of Departments to state “whether they wished to store their records in the Central Archives and, if so, give approximate estimates of the area required.” Before all Departmental Heads could adequately react to the Secretariat circular, political events intervened. On October 20, 1952, *The War of Liberation* prompted the colonial government to declare a state of emergency. Consequently, although the interdepartmental consultations were at an advanced stage with regard to planning for the allocation of accommodation for the housing of public records in the new secretariat office complex (the present Jogoo House “A”), these plans were shelved indefinitely.

The *War of Liberation* affected the development of archives services in various contradictory ways. From 1948 to 1953 (apart from the above-mentioned abortive interterritorial consultations and the cosmetic Kenyan government departmental proposals), virtually nothing meaningful was done to initiate suitable measures for the custody, care, and preservation of public archives, or to introduce proper records management programs within government offices. In 1954, at the height of the *War of Liberation*, however, the colonial administrators suddenly declared that emergency measures should be taken to preserve records of importance which had accumulated over a period of nearly 60 years of colonial domination.

In realizing the prevailing records management problems in public offices in Kenya, the government appointed the first archivist in 1956. The first consolidated plans for a uniform approach to records management in Kenya can be traced back from 1956 when an Archival Circular was issued. Before then, different departments approached their records keeping practices in their own way. Thus, the records management practices of the Provincial and District Commissioners and those of the attorney general and other departments of the colonial regime in Kenya differed from each other and from the practices of the local governments and private companies.

During the years 1975 and 1976, the Department of Kenya National Archives witnessed great changes particularly in its expanded activities. These included the collection, recording, preservation, and conservation of all valuable documents and data for national reconstruction, planning, and development. Some of the materials found in the National Archives of Kenya include many of central and local government records of both colonial and postindependence period. There is a wide collection of

private and public records concerning socioeconomic and cultural activities of national significance and importance.

In order to provide more comprehensive documentation of the social, economic, technological, political, and cultural aspects of African traditional ways of life, additional information has been collected through the recording of oral traditions. Today, this rich oral collection and a well-maintained archival department form the Kenya National Archive, which has become the central national memory system. It now provides valuable resources for planners and administrators, as well as serving the needs of researchers and educators from Kenya and from abroad. If well utilized, the National Archives should therefore become a very important basis for national planning and development. The Archives provides key linkages with the past, present, and future of Kenya.

Legal Framework

Circular No. 1 of 1956 on the implementation of the archival service was issued together with the Rules and Regulations under which the Archivist was to operate. Paragraph 10 of these rules and regulations provided that the government departments should prepare schedules for the disposal of "...files and documents existing or accruing in the department which are considered to be valueless..." In the same circular, the departments were asked to proceed with the scheduling of their records for the preservation and destruction with adherence to the general principles set out in the Archives Rules and Regulations.

The Kenya National Archives was established by an act of parliament, The Public Archives Act of 1965, which took effect on January 25, 1966.

There shall be established, constituted, and maintained a public department to be known as the Public Archives Service for which there shall be appointed a Chief Archivist, and such other staff as may be necessary for the purposes of this Act.

[Section 3 (1)—Establishment of Public Archives Service]

The Act was later revised in 1990 to become The Public Archives and Documentation Service Act, Chapter 19 of the Laws of Kenya. There was a slight amendment in this Section 3 (1) to rename the Public Archives Service to the KNA&DS. Besides the renaming, the position of the Director was created instead of that of Chief Archivist. Notable was also inclusion of Section 5A, that distinctly set up the National Documentation Service and outlined its major roles of which empowered the section to select, collect, process, house, control, and preserve all bound documents created by any government ministry or department.

Records Disposal Act, Chapter 14 of the Laws of Kenya

Circular No. 2 paragraph 6 "Disposal of Records" Section (i) stated that:

"In order to deal quickly with the accumulated backlog of non-current records, the Cabinet authorized the immediate transfer to the Archives of Records dated earlier than 31st December 1945."

This was later developed into The Records Disposal Act in 1962 to take control of the haphazard destruction of public records, in addition to giving guidelines on the kind of records that are to be destroyed.

Other legislation

The *Books and Newspapers Act Chapter 111* names the KNA&DS as a Legal Deposit, in addition to the KNLS and The University of Nairobi Library.

Composition of KNA&DS

The department has seven divisions:

1. Records Management Service.
2. Archives Management Service.
3. National Documentation Service.
4. The Conservation Section.
5. The Audiovisual Archives Section.
6. The Microfilming Section.
7. Support Division (General Administration).

The *Records Management Service* is decentralized with five provincial record centers:

- *Nairobi Records Centre*: Established in 1980 and serves four provinces Nairobi, Eastern, North Eastern, and Central Provinces.
- *Nakuru Records Centre*: Established also in 1980 to serve Rift Valley Province, right from the South to the North Rift.
- *Mombasa Records Centre*: Established in 1981 to serve Coast Province.
- *Kakamega Records Centre*: Set up in 1982 to serve Western Province.
- *Kisumu Records Centre*: Inaugurated in 1989 to serve Nyanza Province.

The main purpose of this service is to provide guidelines to public offices on proper records management practices. This is implemented through developing file classification schemes as well as file retention and disposal schedules. A Provincial Archivist is in charge of each of these activities.

The Archives Management Service is centralized at the department's headquarters in Nairobi. Its main purpose is to provide preservation of public archives (microfilming, storage, audiovisual, and conservation) and access facilities (search room) of the same materials. Efforts have been made to computerize archival lists and catalogs. Users are able to access both manual and online catalogs on archival holdings.

The department has embarked on a digitization project with the purpose of long-term preservation of archives as well as increased accessibility of archival holdings. *The Repository* houses the records within the department. *The Search Room* is the "heart" of KNA&DS as it is the central point from where all the other departments are linked. It has facilities for searching the databases. Any user of the holdings—be it the microfilms, the library books, the records in the repository, etc.—has to pass through this section for the materials to be recalled. Holdings must be used to justify being maintained and thus the strategic importance of the search room.

National Documentation Service (NDS) supplements archival materials with publications. In addition, it facilitates establishment of information resource centers/documentation link centers in public offices. The NDS has six distinct sections:

- The Government Publications Section.
- The Murumbi Africana Collection.
- The Staff Library.
- The Legal Deposit Library.
- The General Publications Section.
- The Periodicals Section.

The Conservation Section has state-of-the-art equipment for conservation purposes. The major role of the department is to restore damaged specimens. In order for information to be available, it has to be preserved and conserved. The department also offers advisory services on the best practices for preservation and conservation of information resources across formats—print, digital, microfilm, etc.

The Audiovisual Archives Section houses a rich collection of still photos on Kenya's heritage; it also houses audiotapes and tape reels about Kenya. All these have information about the rich Kenyan heritage.

The Microfilming Section concentrates on converting print documents to digital formats. Notable are the Kenyan Dailies—the Nation, the Standard, and the Kenya Times. The section has also started digitizing the Murumbi Africana Collection—the rich collection of the late Joseph Murumbi, onetime Kenyan vice president.

Support Division (General Administration): The KNA&DS is headed by a Director, who has two deputy directors; reporting to the deputy directors are the Provincial Archivists and the Heads of the various sections mentioned above.

In addition the KNA&DS maintains an Art Gallery which is one of the major attractions. It has artifacts from throughout Africa. The majority of this collection was bequeathed to the department by the late Joseph Murumbi.

Migrated Archives

When independence was attained on December 12, 1963, the former colonial masters left the country taking public records with them. They argued that these records were created in their tenure, so they were owned by British government. In the *Independence Instruments* (Great Britain, 1962) there was no mention that Britain should hand over to the new Kenya Government "all public archives and records." This very unfortunate omission could have been an oversight or it may have been a deliberate attempt to do away with the records that could provide evidence as to the extent of human rights abuses against Africans during colonial rule. Since independence there has been concerted effort to get those records from Britain. Some have already been received, but others have not and the process is ongoing.

Interministerial cooperation is of great importance to the success of the KNA&DS particularly in the reacquisition and repatriation of Kenya's migrated archives and also in the formation of national information policies and strategies for information collection, preservation, and dissemination. Some of the Ministries involved include: Ministry of Foreign Affairs, Office of the President, Ministries of Finance and Planning, Ministry of State for National Heritage, and the Office of the Attorney general.

Other Kinds of Repositories

Most institutions in Kenya manage their archival repositories privately. However, the Kenya Ports Authority's archives are managed with the help of the KNA&DS. Others like the National Museums of Kenya have their autonomously functioning archives.

Many companies and financial institutions also have archives, which are managed independently.

Finding AIDS

The National Archives has two kind of finding aids: manual catalogs and online databases. Each department has a database. For example, the library has an NDS database

running on CDS/ISIS Automation Software. Other databases include:

- An AV database.
- An archive database for records management.
- The JNL database for journals.
- The DOCA 9 for court records.
- A microfilm database.

Cooperation

The department is trying to cooperate with librarians, documentalists, and information specialists in other fields with an aim of adopting modern techniques of storage, retrieval, and conservation.

The department has ventured into partnership with several organizations such as:

1. The Kenya Anti-Corruption Commission, with the purpose of enhancing effective records management since records are the cornerstone to accountability and transparency, a factor underpinning good governance and ensuring corruption free nation.
2. The Murumbi Trust Foundation, which has assisted in the refurbishment of Murumbi Art Gallery Exhibition. Because of this renovation, the department has been able to attract many more viewers to the gallery.
3. The FORD foundation, with the purpose of improving the management of audiovisual records, in terms of capacity building and provision of equipment.
4. Professional bodies, both regional and international bodies such as:
 - International Council on Archives (ICA).
 - Eastern and Southern Africa Regional Branch of ICA (ESARBICA).
 - Association of Commonwealth Archivists and Records Managers (ACARM).

Through interaction with these bodies, the department is able to keep abreast with current trends in the profession.

Training Institutions

Most of the training of Kenyan archival professionals was initially done in India and the United Kingdom. University training of information professionals in Kenya and especially in the archival field is in its relatively “early” stages. Archival training was first offered at Moi University where the Faculty of Information Sciences was inaugurated in 1988; the first students in Archival studies graduated in 1992. However, due to the increased demand for information workers in this area, even private tertiary colleges are now taking the cue and are offering archival courses in their curriculum. The following is a brief summary of this training in Kenya.

Moi University was the pioneer institution in Kenya for archival training at the undergraduate degree level. It offers programs in Librarianship, Archival Studies, Publishing and Book Trade, and Information Technology. The students specialize in their chosen field during their final year(s) of study. There is also postgraduate training in these same fields and both M.Phil. (Master of Philosophy) and M.Sc. (Masters in Science) Programs in Records and Archives Management are offered. The former is for those students with a background in information science and the latter for those who are interested in an archives and records management career and already hold a graduate degree in another field.

Kenyatta University has a postgraduate program—M. Sc. in Records and Archives Management. Most of the staff members at the National Archives have completed, or are in the process of completing this program.

Egerton University trains graduates in information work and among the units is archives and records management.

Kenya Polytechnic is a public institution. It was the pioneer trainer of information workers in the country but at “lower” academic levels offering certificates and diplomas. Currently, it has a Higher National Diploma in Records Management, Ordinary Diploma, and Certificate in Records Management.

Sigalagala Training Institute is also a public institution training at both Diploma and Certificate levels.

Kenya School of Professional Studies—Inoorero Centre is a privately owned tertiary institution that trains archival and record management workers at Higher National Diploma, Diploma, and Certificate level. Its affiliate School of Professional Studies, Thika Road, trains at diploma and certificate levels. It also offers Degree training through distance learning in collaboration with UNISA—University of South Africa.

Railway Training Institute is a college that trains information workers at both diploma and certificate levels. Among the units is archives and records management.

Personalities who contributed to records management in Kenya

- *Sir Percy Girourd*, 1910—He issued the first circular toward streamlined records management in Kenya.
- *Derek Charman*—He was the first archivist.
- *Nathan Fedha*—The first African archivist.
- *Joseph Murumbi*—while in the archives council of 1977/1978 had good ideas for the running of the archival service. Apart from that his rich collection of manuscripts, books and, artifacts is still housed within the KNA&DS. He also requested Professor Bethwel Ogot of University of Nairobi to outline strategic projections, functions, and resources necessary to sustain and develop an archive service.

- *Professor Bethwel Ogot*—He consulted a number of leading authorities on the subject, particularly works of Sir Hillary Jenkinson and wrote a well-documented paper which was later used by Murumbi to gain support for the establishment and development of archives from the Kenyatta cabinet.

In conclusion, it is important to note that there is a general realization of the role of records for good governance. Despite the sorry state of the archival service in the “earlier” years, currently there have been concerted efforts to improve on the same.

MUSEUMS AND MUSEOLOGY: NATIONAL MUSEUMS OF KENYA

The concept of museums in Kenya (and Africa as a whole) is a foreign import. While sacred and ritual artifacts were kept in the courts and palaces and homes of Kings and Chiefs, in practice these were for ritual purposes only and each object had its meaning. Objects were never collected. The first museums in Africa started in the early nineteenth century and were colonial institutions created to display African cultural and natural heritage in order to entertain and amuse an elite group of Europeans. In addition, much of African heritage occupies large spaces in some of the biggest museums around the world.

Historical Background

The history of the National Museums of Kenya (NMK) dates back to 1910 when a museum was established in Nairobi by the then East Africa and Uganda Natural History Society (currently the East African Natural History Society). The membership consisted mainly of colonial settlers and naturalists who collected artifacts and specimens for their own enjoyment and study, but also with the goal of making a critical scientific examination of the East African environment. The Society needed a place to keep and preserve their collections of various specimens, and this necessitated the establishment of a museum. Its first site was at the present Nyayo House which soon became too small. A larger building was constructed in 1922 where the Nairobi Serena Hotel stands.

It was not until 1929 that the colonial government set aside land at the Museum Hill and construction work started at the current site. The new building was officially opened on September 22, 1930 and named Coryndon Museum in honor of Sir Robert Coryndon, onetime Governor of Kenya and a staunch supporter of Uganda Natural History Society. On the attainment of independence in 1963, it was renamed the National Museums of Kenya. Since the 1960s, NMK has expanded its services and assets to include regional museums, and has acquired

under its jurisdiction sites and monuments which the government has set aside as monuments of national heritage. Each of the Regional Museums has its own identity and develops its own programs. The museum has also established collaborations, research, and development programs, such as the Institute of Primate Research and Research Institute for Swahili Studies in East Africa.

Before the Museums Act 2006 became operational, it is important to note that from its humble beginnings, the Museum grew into a research institution of international repute, which boasted over 20 research departments, various museums, sites, and monuments open to the public; these are spread across the country's eight provinces.

NMK Legislation

The NMK was initially established as a corporate body under the Ministry of National Heritage, drawing its mandate from two Acts of Parliament: the National Museums of Kenya Act (Chapter 216) and the Antiquities and Monuments Act (Chapter 215) both passed in 1983. These Acts have been reviewed and have been merged into what is known as the Heritage Bill 2006, which was recently passed into law by Parliament.

In the early years of its development, the NMK established itself as a research institution of great international repute, especially in the field of paleontology where the search for human origins yielded some remarkable finds resulting in the famous collections of hominid and other fossils. However the period of the 1980s was characterized by a low level of activity in the public domain. Little was done to draw attention to the research carried out by the museum and its relevance to the public it served. At the time besides exhibitions and a modest school education service, little else was done to encourage the public to visit the museum. Public criticism emerged, centered on the fact that the results of scientific research, leading to many useful discoveries and breakthroughs, were hardly communicated to the public. The token activities in the area of public programming included activities such as guided tours, lectures, and slide talks, and these programs tended to dwell more on the objects than on the contexts which they represent. This resulted in the view of the museum as a boring stuffy place full of old relics.

Presently, the NMK is a state corporation established by an Act of Parliament, the Museums and Heritage Act 2006. NMK is a multidisciplinary institution whose role is to collect, preserve, study, document, and present Kenya's past and present cultural and natural heritage. This is for the purposes of enhancing knowledge, appreciation, respect, and sustainable utilization of these resources for the benefit of Kenya and the world, for now and posterity.

In addition, NMK as the custodian of heritage in Kenya manages Regional Museums, Sites, and Monuments of national and international importance alongside priceless collections of Kenya's living cultural and natural heritage.

Nairobi Museum

Nairobi Museum is the flagship Museum managed by the NMK. The newly expanded and refurbished museum opened recently with double the exhibition space, brand new exhibitions, and a new name: The Nairobi National Museum. It has as its slogan, *The Place of Discovery*.

The new museum reflects the repositioning of the NMK as the country's dynamic heritage management institution. In an effort to portray a vibrant and enjoyable place for experiencing cultural heritage, the NMK undertook a re-branding exercise that has seen the Nairobi Museum become a one-stop shop.

Through the years, the NMK has grown to become one of regional and international importance. The museum has become a leading center of excellence, housing some of the finest museum collections and exhibits on the continent. Over the years, the NMK was faced with the challenge of justifying its relevance to the public and the need to generate revenue. NMK begun to recognize the need to become more responsive to demands and the changing needs of its wider public without losing sight of its mission.

Thus these demands have required that the museum redefines its vision and become responsive to the current needs of society in order to remain relevant. NMK recognized that sustainable support depends on the museums' contribution to national development through addressing issues that affect its communities. NMK thus has attempted to change its image of "static exhibit showcases of the past" which it acquired from its Eurocentric history. Its goal has been to move toward a more dynamic contemporary image, departing from the outdated view that museums exhibit "old relics," and instead creating a place where people from all walks of life meet and have dialogue on various socioeconomic issues. In 2002, the NMK with support from the European Union (EU) embarked on a refurbishment and expansion effort known as the "Museum in Change" program. This program was funded by €8 million donated by the EU within the framework of National Museums of Kenya Support Program. These funds were used for the renovated and expanded exhibition space in Nairobi Museum which was completed at the end of 2007. The program work which begun in 2002 has resulted in the development of an institutional strategic plan for public programming 2005–2009, the basis upon which NMK is evaluating its policies.

With the expansion of its mandate and with the dynamic environment in which it operates, the NMK had to redefine its operations to become more responsive to the changing circumstances. In order to keep abreast with changes in the environment in which it is operating, the NMK has developed programs that promote cultural dynamism in order to build a sense of nationhood and belonging.

Regional Museums

In terms of the management of heritage within the country, the NMK continues to expand its regional Museums network and prepare many of its important sites for listing on the prestigious World Heritage List as well and the list of endangered sites. The regional museum network serves as a means for the NMK to reach a wider segment of the population. While most of the research and collections are concentrated at the NMK headquarters in Nairobi, the regional museum network also provides galleries and sites for interpretation of various aspects of the country's heritage. This regional concept was developed in the 1980s in accordance with UNESCO guidelines to bring museums to the people and it is meant to cater for the needs of the population in regions away from the Capital Nairobi. Two of the first purpose-built regional museums are located in the west of the country, in Kisumu and Kitale, and have exhibition on natural and cultural history of the region. Some of the regional museums established in historic buildings can be found in Lamu, Malindi, Mombasa, Meru, Karen, Kabarnet, and Kapenguria. Other museums opened their doors to the public in Gede, Narok, Gilgil, Nakuru, and Loiyangalani.

The main aim of all regional museums is the presentation of Kenya's natural and cultural heritage, with special programs to create awareness for the preservation and sustainable utilization of the country's heritage. The regional museums furthermore specialize in particular areas of interest relevant to the regions they serve. Some regional museums have live displays of reptiles and fish, while others have traditional homesteads of the communities in the region.

Apart from regional museums, the NMK has developed over the years a number of sites and monuments and equipped them with interpretation and visitor facilities. The coastal region has many of these sites located in ruined Swahili settlements that date from the thirteenth to seventeenth centuries A.D.; examples include the Takwa, Gede, Mnarani, and Jumba La Mtwana Ruins. Three military monuments are open to the public, Siyu Fort on Pate Island, Lamu Fort on Lamu Island, and the world famous Portuguese-built Fort Jesus on Mombasa Island.

Three religious monuments can be visited:

- The Portuguese chapel in Malindi from the time of the Portuguese supremacy over the Indian Ocean trade.
- The architecturally unique Kongo Mosque, on the beach in Diani, South Coast, which is still in use by the local community.
- Krapf Memorial Site, an interpretation of early Christianity in East Africa, is the first Christian church in Kenya, completed in 1848, when missionaries endeavored to ensure abolition of the slave trade. Related to the latter subject is Shimoni Cave on the South Coast, a community program in conservation of a historically important cave and in tourism development.

Numerous other sites are under the custodianship of NMK but are not yet open to the public. One of them is Mtwapa Ruins, a large ruined Swahili settlement that was included on the World Monuments List of most endangered sites in 2004.

Karen Blixen Museum

This museum was once the home owned by the Danish author Karen Blixen and her Swedish husband, Baron Bror von Blixen Finecke. Located 10 km from the city center, the museum belongs to a different time period in the history of Kenya, and its architecture is typical of the kind of homes built by European settlers in the early years of the twentieth century. The house and the farm at the foot of the Ngong Hills gained international fame with the release of the movie *Out of Africa* an Oscar-winning film based on Karen's autobiography by the same title. The popularity of the film prompted the opening of Nairobi's Karen Blixen Museum.

The house was sporadically occupied until purchased in 1964 by the Danish government and given to the Kenyan government as an independence gift. The museum was opened to the public in 1986. Many pieces of furniture that Karen Blixen sold to Lady McMillan on her departure were reacquired and constitute part of the exhibition in the museum. The museum house remains a serene environment that seems to belong to the past, surrounded by a tranquil garden and indigenous forest, with a splendid view of Karen Blixen's beloved Ngong Hills. Whereas most regional museums have a good proportion of both foreign and local visitors, the Karen Blixen Museum generates most of its revenue from international visitors.

Fort Jesus Museum

Fort Jesus was built in 1593 by the Portuguese to solidify their power on the East African Coast, but the fort changed hands several times between the Portuguese and the Omani Arabs. The British also used the fort as a prison during the colonial period. Today it is a national monument and a popular museum, which displays ancient artifacts of the coastal life. It also holds a conservation laboratory, a gift shop, and a cafeteria. Part of the museum is in the Old Law Court, which holds a research library, coastal archeology department, and a regional center for archeological study.

Lamu Museum

One of the oldest towns along the East African Coast is Lamu town, located on Lamu Island north of Malindi. This Swahili town is said to have been founded around the tenth century. It used to be a very busy port in the eighteenth and the nineteenth centuries. The Old Fort in the center of the town built in 1812 is today a cultural

center. The town has numerous Museums such as the Swahili House Museum, the German Post Office Museum, the Lamu Fort Environment Museum, and the Lamu Museum. The Lamu Museum occupies what used to be the District commissioner's house, a house originally built for Queen Victoria's consul, Jack Haggard. This museum houses a rich collection of ethnographic material from the Swahili, Orma, and Pokomo ethnic groups. Also on display are the traditional Swahili crafts such as the Siwa (side-blown horn), furniture, and jewelry. The Island town of Lamu can only be approached by boat. It served as a prison from 1910 to 1984, and was used by both the British colonial regime and the Kenya government, before it was handed over to the NMK in 1984. Efforts to turn the Fort into a museum were started with technical and financial assistance from Swedish International Development Agency. From its inception, the museum had environmental conservation as its general theme; Lamu Fort is basically a community center for the people of Lamu old town.

Lamu World Heritage Site

However, the crown jewels of NMK's assets at the coast are:

- *Lamu World Heritage Site*: In December 2001, Lamu Old Town Conservation Area was inscribed on the UNESCO's World Heritage List to protect and conserve its rich and unique cultural and architectural heritage, as a major contribution to the development of humankind. NMK has six assets in Lamu Old Town, which is the oldest surviving Swahili town of the entire East African coast and Indian Ocean islands. The operation of Lamu Museums is—more than anywhere else—very much intertwined with the lives of the people and the activities of the local authorities.
- *The Miji-Kenda Kaya forests* which were listed on the World Heritage List at the 32nd Committee of the World Heritage Convention in Quebec, Canada, July 2008.
- *Fort Jesus* which has also been proposed for World Heritage listing. It is expected that Fort Jesus and Mombasa Old Town Conservation Area will soon be declared a World Heritage Site, because this important site represents the millennium-old human history of the East African coast. At various points in time, the Portuguese, Omani Arabs, the British, the Baluchis, and the Indians were present at one time or another in Fort Jesus.

Archeological and Paleontological Sites

Kariandusi, Olorgesailie, and Koobi Fora: Kenya is home to some of the most renowned paleontological/archeological sites in the Great Rift Valley. Both

Olorgesailie and Kariandusi sites represent the Acheulian Culture of the Early Stone Age. Koobi Fora in Sibiloi National Park is a mixed World Heritage Site and home to important early hominid finds. Visitor facilities in these Rift Valley sites include an interpretation gallery and accommodation facilities. All NMK sites are very strategically located and offer often breathtaking panoramic views of the surrounding landscape at the bottom of the Rift Valley.

Thimlich Ohinga: In Kenya's Lake Victoria region is Thimlich Ohinga Cultural Landscape, nominated by the World Monuments Watch into the list of the 100 most endangered sites for the period 2000/2001. Thimlich Ohinga is a fine example of a complex of dry stone wall enclosures and is sometimes referred to as the Great Zimbabwe of East Africa; it represents the same indigenous building technique in the form of circular interconnected defensive structures.

Historical sites

Kapenguria Museum: While some sites and monuments are reminders of the colonial period (old Provincial Commissioner or District Commissioner offices or residences), other sites evoke the country's political history and mainly the struggle for independence. Two sites (Kapenguria and Lokitaung) are prisons where the founding fathers of the nation were detained, while two other sites (Lodwar and Maralal) are residential houses where the first president, Mzee Jomo Kenyatta, was kept in isolation after his release from prison and before they signed the declaration of independence.

Uhuru Gardens: Uhuru Gardens in Nairobi is the park where the first flag was raised by the first president on the night of independence. Currently, a "Heroes and Heroines Square" is being developed there to commemorate all those who contributed to the liberation and nation building.

Education for Curators and Museum Administration

For continuous capacity building in the various fields in the museum, the NMK together with other stakeholders in the region started an international nongovernmental organization previously known as Program for Museum Development in Africa (PMDA) dedicated to the preservation, management, and promotion of cultural heritage in Africa through a program of training and development support services.

Since its inception in 2000, PMDA, now known as Centre for Heritage Development in Africa (CHDA), has become recognized for the quality and innovative character of its training and development support programs and activities that it provides to professionals and institutions responsible for movable and immovable heritage in

English-speaking sub-Saharan Africa. CHDA works in close collaboration with the University of Nairobi and is supported in its programs and activities by funding and technical partners throughout the world.

For its future activities, CHDA intends to pay special attention to ensuring the better utilization of museum collections for public programs and to making museums play a positive role in the lives of children.

Because of its diverse and strategic roles, the NMK plays host to a number of regional and international programs as well as collaboration projects. Some of these are Africa 2009 Program, Koobi Fora Field School, a joint program with the Rutgers University in New Jersey.

Professional Associations

International Council of African Museums

Of special note, is the establishment of the International Council of African Museums (AFRICOM), a professional association that brings together museum and heritage professionals in Africa and is housed within the NMK. The AFRICOM Program was born as an outcome of the Encounters "What Museums for Africa? Heritage in the Future" organized by ICOM in Benin, Ghana, and Togo in November 1991. The aim of the encounters was to address the role and the relevance of the museum for the African continent. The African professionals drew up a program addressing issues considered as priorities. In September 1992, this program was adopted by the General Assembly of ICOM within its Triennial Programme of Activities for 1993–1995 at ICOM's General Conference in Quebec. Its major objective was to develop exchanges among professionals of the continent and outside of Africa, and to consolidate the regional professional networks.

AFRICOM was created to help the continent promote the development of museums and museum-related institutions in Africa in the context of global development and to promote the development of professions on which museum activities are built, strengthen collaboration and cooperation among museums and its professionals in Africa, promote participation of all components of the society in the protection and enhancement of cultural and natural heritage among other activities. Membership is mostly African but museum professionals and partners around the globe are encouraged to participate in its activities.

International Committee of Museums

Other museum professional bodies include the International Council of Museums (ICOM), which brings together museum professionals from all over the world. ICOM is different from AFRICOM and it is more committee-oriented depending on one's professional specialty. For example, those responsible for marketing and public

relations (MRP) within the museum would be members of the MPR committee of ICOM.

Societies

The NMK also plays host to various societies that work closely with the institution to either raise funds for projects within the various museums or to increase public awareness of the heritage of Kenya or bring together those with a particular field of interest. Some of these include:

- Kenya Museum Society
- Malindi Museum Society
- Friends of Fort Jesus
- Kenya Prehistory Club

Museology as a Discipline and Profession

From the discussion above, it is clearly evident that NMK is a diverse and complex organization with a broad mandate and a wide range of activities. However there is a need for continuous capacity building in the area of museum training which until recently was not seen as the kind of knowledge needed to manage a museum. It must be noted that African museums were largely founded during the colonial era to house artifacts that were collected out of curiosity by colonists, who often assembled these collections as a means of trying to understand African culture and customs which were believed to be “backward” and “primitive.”

With museums burgeoning all over the world, there was need for the identification of a clear role for museums in society and there gradually developed a body of theory and practice which is known as museology. Museum professionals were nearly always trained in a discipline related to a particular collection, and therefore they had little understanding of the museum as a whole, its operation, and its role in society. As a result, the practical aspects of museum work, for example, conservation and exhibition development were achieved through borrowing from other disciplines and other techniques, whether or not they particularly met the requirements of the museum and its public. This is still the case in Kenya as there are no local universities or educational institutions offering Museology as a discipline. The only disciplines offered that may be closely related include anthropology and archeology. To study museology, African museum professionals have to apply to universities outside of the African continent thus making this a great challenge for museums in terms of capacity building. It is also difficult for museologists to work in isolation as they may need the expertise of other specialized disciplines in the development and curation of exhibitions.

On the other hand, through collaboration with other institutions and partners, Kenyan museums have been able to send some staff on exchange programs that

culminated in extensive projects that brought together people from different disciplines to develop significant exhibitions and programs. For example, in 2006, the NMK in collaboration with the British Museum were able to host an exhibition of the Hazina (Treasures). For this exhibition, a huge collection of artifacts from the East African region that are held by the British Museum were brought to Kenya for the very first time. Other important collaborations include the Koobi Fora Field school which is organized in partnership with Rutgers University in New Jersey, United States. Students from the United States and local students come together to acquire skills in hominid collections. The University of the Western Cape and The University of Cape Town in South African saw a gap in museum training on the continent and designed a postgraduate course for African professions titled the African Programme for Museum and Heritage Studies in Africa.

Key Contemporary Issues, Access, Preservation, and Educational Role

On October 15, 2005, the museum was partially closed, launching a project for a major expansion supported by the EU. The year 2008 marked an extraordinary milestone for the NMK as the institution began a historic transformation with the opening of the New Nairobi Museum.

The end result was the opening on July 14, 2008 of a state-of-the-art facility with new exhibitions and larger exhibition galleries as well as a new visitor center. The museum also features an array of new visitor amenities including restaurants and shops that will make the museum a one-stop shop.

Essential to the transformation of the Nairobi Museum are the goals of increased accessibility to the collections for students, scholars, and the public and enhanced collaboration and interdisciplinary work across all departments and collaborators.

The new and renovated museum offers greatly enhanced flexibility for viewing, studying, and interacting with the collections while providing dynamic museum experiences for visitors and establishing an innovative new model for object-based learning.

Outstanding Personalities

1. Sir Arthur Loveridge—first paid museum curator in 1914
2. James Maikweki—first African curator
3. Louis and Mary Leakey—renowned paleontologists
4. Richard and Meave Leakey—renowned paleontologists
5. Dr. Mohamed Isahakia—first Black African Director General, NMK
6. Rev. Kenneth St. Aubyn Rogers—founder of the East African Natural History Society (Now Nature Kenya)

Museums the world over are reexamining their traditional responsibilities to society. New demands are constantly being placed on museums to be accountable and relevant to the communities that they serve. In Kenya, this process of “new” museology is heightened by the sociopolitical changes that are taking place. In order to survive, the NMK is working hard to shake off its former static, “don’t touch” image to be more participatory, user friendly, and sensitive to its visitors.

The NMK remains committed to the development of arts and culture in the country and continues to work with the other stakeholders in the study of our modern and contemporary collections, in keeping with the transformation shaping museums around the world. NMK must be seen to endeavor to contribute to developing national consciousness by unifying the country using its collections to sensitize Kenyan people to economical, social, and political issues.

The NMK also continues to present diverse and enlightening programming that offer new opportunities and challenges to our curatorial, education, programming staff who must draw on their creative talents and utilize the great resources at NMK. At the same time, the prospect of working in partnership with institutions outside the NMK represents another exciting opportunity for the NMK.

CONCLUSION

Kenya is well aware of the fact that the world has changed to an information-driven economy. Major stakeholders have taken various steps to include information in every sector of development. In view of increased demand for library and information services, the KNLS has adopted the community-based library initiative which aimed at accelerating library development in the country. The major public, academic, and special libraries in Kenya are embracing ICT in their operations and service delivery.

There is a general realization of the role of records for good governance. Despite the sorry state of the archival service in the “earlier” years, currently there have been concerted efforts to improve on the same.

The NMK remains committed to the development of arts and culture in the country and continues to work with the other stakeholders in the study of our modern and contemporary collections, in keeping with the transformation of museums around the world. NMK must be seen to endeavor to contribute to developing national consciousness by unifying the country using its collections to sensitize Kenyan people on all fronts economical, social, and political.

The dissemination of information in Kenya relies too much on the printed word, which is not accessible to all Kenyans. The press, libraries, museums, archives, various information centers, and broadcasting services

cannot really satisfy the information needs of Kenyans. The ICTs have become central to information dissemination. In the government’s Vision 2030 development strategy, the country plans to introduce digital villages in both urban and rural areas by 2030. This will facilitate easy and faster information flow, thus propelling economic development. The government of Kenya must formulate favorable policies that would encourage the use of ICT. It is important to note that LIS schools in Kenya have embraced the use of ICTs and introduced them in the curriculum.

Knowledge

Paul K. Moser

Arnold vander Nat

Department of Philosophy, Loyola University Chicago, Chicago, Illinois, U.S.A.

Abstract

Among Western philosophers, the study of knowledge emerged in ancient Greece, under the definitive influence of Plato and Aristotle. Plato's *Theaetetus* immortalized the view that knowledge consists of justified true belief, and this view has come to be called "the traditional analysis of knowledge." This entry outlines the traditional analysis, and presents a formidable threat to it: the Gettier problem.

INTRODUCTION

Human knowledge naturally falls into various categories: empirical (or, a posteriori) knowledge, nonempirical (or, a priori) knowledge, knowledge by description (a kind of propositional knowledge), knowledge by acquaintance (a kind of non-propositional knowledge), and knowledge of *how* to do something. Empirical knowledge depends for its evidence, or justification, component on sensory experience, whereas nonempirical knowledge depends for its evidence component solely on what Kant called "pure reason" or "pure understanding." Although current understanding of the distinction between a priori and a posteriori knowledge stems largely from Kant,^[1] earlier variations on the distinction are found in Leibniz and Hume. Knowledge of physical objects serves as a standard example of empirical knowledge, whereas knowledge of logical and mathematical truths provides a typical instance of nonempirical knowledge. Knowledge of logical and mathematical truth seems not to depend on sensory experience for its evidence component.

Bertrand Russell^[2,3] famously distinguished between propositional knowledge by description and non-propositional knowledge by acquaintance. Knowledge by description includes knowledge *that* something is the case, whereas knowledge by acquaintance includes direct non-propositional awareness of something, and does not necessarily include knowledge that something is the case. We shall focus on the traditionally required components of propositional knowledge that something is the case: belief, truth, and justification.

Belief

Propositional knowledge requires belief, but belief does not entail knowledge. We cannot know, for example, that pomegranates are red without believing that they are red. Propositional knowledge is belief that satisfies the *truth*

condition and the *justification*, or evidence, condition for knowledge.

Philosophical controversy arises over what exactly beliefs are, and yields two prominent views: a *dispositional view* and a *state-object view*. The dispositional view implies that beliefs are just *dispositions to act in a certain way*, and receives support from Charles Peirce and Gilbert Ryle, among others. According to this view, believing that the food before me is deadly is just to be disposed to act toward it in a manner appropriate to its being deadly. Identifying beliefs with dispositions to act gives beliefs a practical function that they might otherwise lack. If beliefs are just dispositions to act, then beliefs will figure centrally in the motivating forces of actions; and they evidently do.

The view that beliefs are just dispositions to act must confront a serious problem. We often invoke beliefs, including their propositional objects indicated by a "that"—clause, to explain why we do what we do. We say, for instance, that I ate the pomegranate *because* I believed that I was hungry and that eating it would satisfy my hunger. The dispositional view implies that I ate the pomegranate because doing so was part of a disposition of mine to behave in certain ways. This view fails, however, to account for the role of the relevant propositional *content* in my behavior: namely, the belief-content that I was hungry and that my eating the pomegranate would satisfy my hunger. We typically explain actions in ways that rely on the propositional contents of beliefs, but the dispositional view of belief does not allow for this. It omits propositional contents, and thus precludes the central role of such contents in the explanation of actions.

The *state-object view* of belief seems more promising than the dispositional view. It implies that belief requires a special relation between a person and an *object of belief*. It thus distinguishes a person's *state* of believing and an object of belief, that is, what is believed. On this view, to believe that pomegranates are red is to be related in a special way to an object of belief. The objects of belief,

according to a prominent view from Frege, are *abstract propositions*, which are nonphysical entities that exist independently of anyone's thinking of them. They are similar to numbers and other mathematical objects as represented by Platonists. The special relation of believing, according to many philosophers, is a *propositional attitude* that involves some degree of confidence toward a propositional object of belief. Endorsed by Frege,^[4,5] Russell,^[6] and Moore,^[7] among others, this view aims to make sense of how two persons can believe *the same thing*: for example, that pomegranates are red. Each person has *access* to one and the same abstract proposition, and each can have the attitude of believing that proposition.

A familiar problem concerns the supposed realm of abstract, nonphysical propositions, which many proponents regard as eternal, infinite in number, and accessible by an act of the human mind. Philosophers with physicalist inclinations have doubts about the existence of such a realm, and they regard the supposed special relation of believers to that Platonic realm as unacceptably mysterious. They demand a view of the intersubjectivity of belief that adds to its intelligibility and plausibility without increasing mystery.

Seeking to avoid mystery, some philosophers, including Rudolf Carnap^[8] and Quine,^[9] hold that the objects of belief are *sentences*. We need to distinguish between a sentence *token* and a sentence *type*. A sentence token is a physical sentence resulting from someone's speaking or writing, whereas a sentence type is the abstract class of all such sentence utterances or inscriptions that have the same form. Each utterance of "It is red," for instance, is a member of the abstract class of all such utterances, and is thus a token of that sentence type.

If the objects of belief are sentence tokens, the belief relation between a person and an object of belief is relatively straightforward, since physical occurrences can be intelligibly related to in various ways, for example, causally. There is, however, a difficulty for this view: if the objects of belief are inscriptions and utterances, a person not now related to such tokens does not now believe *anything*, since there is no object of belief for that person. This is a real problem, given the familiar position that there can be beliefs in the absence of physical inscriptions and utterances.

One might seek refuge in the view that the objects of belief are sentence *types*. Even if a person is not now related to an inscription or utterance, an abstract sentence-type can still be the object of belief so long as the person has a belief relation to it. Still, many philosophers will wonder whether abstract sentence-types actually exist. If they do, can a person have a belief relation to such an abstract entity, and what kind of mechanism or process is at work between the two? In addition, can a person have a belief relation to an abstract type without having a similar relation to a physical token of that type? If not, why

should we hold that the presumed role of abstract sentence-types is ineliminable?

We should mention a traditional view on the objects of belief suggested by Aristotle, certain medieval scholastics, classical modern philosophers such as Descartes, Locke,^[10] Hume, and Kant, and contemporary thinkers such as Noam Chomsky^[11] and Jerry Fodor.^[12] This view entails that the objects of belief are *mental, or psychological, propositions*, rather than abstract propositions. That is, they are the *thoughts* we think as we live our lives. Of course, we can *express* our thoughts in words or in some other manner, but typically our thoughts are not expressed at all. Mental propositions belong to the mental life of an individual and have no existence apart from that life. The mental-proposition view avoids problems involving a realm of Platonic objects that exist independently of us and our thoughts. Since mental propositions are psychological particulars in the mental life of a person, the belief relation between a person and an object of belief is not obviously troublesome. Improving on the sentence-object view, the mental-proposition view allows that the objects of belief can be expressed in various natural languages, and may even be altogether unexpressed.

Many philosophers will press the issue of what exactly mental propositions, or thoughts, are. In addition, they will ask how we can account for the evident fact that some people believe *the same thing*, if mental propositions are the private thoughts of an individual. They will also ask how there can be verbal communication between individuals if thoughts are private? Wittgenstein^[13] may have had such a worry in his famous discussion of private languages.

We have contrasted dispositional and state-object views of belief, because belief is a necessary component of propositional knowledge. Two other necessary conditions for such knowledge merit comment: truth and justification.

Truth

I know that all pomegranates are red only if it is true that all pomegranates are red. If there are pomegranates that are not red, but are walnut black, then I do not know that all pomegranates are red. So, knowledge requires truth. It is false, then, that astronomers before Galileo *knew* that the sun moves around the earth. Since it is false that the sun moves around the earth, no one *at any time* knows that the sun moves around the earth. Of course, one might believe, even justifiably believe that the sun moves around the earth, since neither mere belief nor justifiable belief requires truth. Even so, propositional knowledge without truth is impossible, according to the traditional conception of such knowledge.

The question of what truth is does not ask what the standards are for discerning truth. Our standards for discerning truth concern our ways of *finding out* what is true

and what is not true. The question of what truth is, in contrast, concerns the nature of truth, or what constitutes truth. We might rephrase the question as: what does it mean to say that something is true? Someone could know what it means to say that something is true, but lack a standard for finding out whether a particular proposition is actually true. We shall note three approaches to truth that philosophers have proposed for capturing the truth condition of propositional knowledge: correspondence, coherence, and pragmatic theories.

Correspondence

Many philosophers, including Moore, Russell, and the early Wittgenstein, have held, in the tradition of Aristotle that truth consists in a *correspondence relation* between truth-bearers that state something and features of the actual world. According to a correspondence theory, true statements represent how the world is in virtue of their “corresponding” to some aspects of the actual world, that is, to some actually existing situation. This is an account of what constitutes truth, not of how we tell whether a statement is true.

A key issue concerns the exact sense in which a true statement, such as, “The earth orbits the sun,” *corresponds* to reality. It is difficult to capture the pertinent sense of correspondence, and thus no exact account of correspondence has come to be shared by philosophers. Correspondence is not literal “picturing” of the world by true statements, because many true statements are not literal pictures of what they are true of. Consider true statements that are negative (“It is not the case that the sun orbits the earth”), or true statements that involve unrealized conditions (“If the sun explodes, life on earth will cease”), or true statements about nonempirical matters (“Nothing can be both a triangle and an octagon”). Such truths do not literally picture what they are true of, or what makes them true. It is unclear, in addition, how exactly they “correspond” to what they are true of. Proponents of a correspondence theory must identify the kind(s) of correspondence that obtains for true sentences, including those just mentioned.

Mackie^[14] and others have endorsed the following “simple” view of truth, in the light of problems concerning the nature of correspondence: to say that a statement is true is to say that whatever in the making of the statement is stated to obtain does actually obtain. This view has affinities with Aristotle’s position that truth is a statement of what is that it is or a statement of what is not that it is not. Mackie opposes Ramsey’s^[15] “redundancy” view of truth, which states that the predicate “is true” is eliminable because it adds nothing to a statement to which it is applied. On the basis of the simple view, Mackie denies that the statement that *P* is true is just a re-affirmation of the statement that *P*. According to the simple view, truth is a distinctive relation, as identified by the simple view,

between a statement and an actual situation. A statement that does not ascribe truth thus does not necessarily ascribe the truth relation in question. The simple view is a minimal correspondence theory in virtue of its characterizing truth as a relation between a statement and an actual situation.

Alfred Tarski’s^[16] “semantic approach” to truth is a correspondence theory, according to some philosophers. This approach offers the following principle not as a definition of truth but as a necessary condition that must be met by any acceptable definition of truth: *X* is true if and only if *P* (where “*P*” stands for a declarative sentence, and “*X*” stands for an expression that refers to *P*.) Accordingly, the sentence “All pomegranates are red” is true if and only if all pomegranates are red. What follows “if and only if” in Tarski’s necessary condition connotes an existing situation to which the pertinent true sentence is appropriately related. Various philosophers have thus understood Tarski’s necessary condition as specifying a correspondence requirement on truth.

Even if we had an adequate explanation of the correspondence definitive of truth, we would still face a difficult epistemological question in combining a correspondence approach with a claim to knowledge. How can a person *know* that a correspondence relation actually holds between a statement and the world? In particular, how can a person be *justified* in believing that such a relation holds? If truth is correspondence, then to know that a proposition is true, a person must know that a correspondence relation obtains. Are we thus required to compare a proposition with the way the world is and thereby determine that the proposition corresponds to the world? In that case, to show that we have the knowledge in question, we apparently need an independent means of access to the way the world is. Some philosophers contend that we lack such a means of access, and thus hold that a correspondence theory of truth raises insurmountable problems when joined with claims to knowledge. Even so, a correspondence theory of truth does *not* entail that a person must *know* that the correspondence relation obtains. It entails rather that a statement is true simply because the correspondence relation does obtain, even if no one knows that it obtains. The correspondence relation definitive of truth is not offered as a knowledge-dependent and relation.

Coherence

A coherence theory of truth aims to characterize truth without reliance on talk of correspondence relations. In short: to say that a statement is true is to say that it “coheres” with a specific comprehensive system of statements. The fact that a set of statements is suitably interconnected or systematic (i.e., “coherent”) is thus offered as being definitive of truth. This approach to truth has been endorsed by Spinoza among others,^[17] and it is

offered as capturing what is constitutive of truth, and not only as a test of truth. Logical implication is the strongest kind of coherence, and some proponents of the coherence theory appeal to it to illustrate the kind of coherence that characterizes truth. These proponents typically regard the system of mathematical truths as being a standard coherent system yielding truth.

Proponents of a coherence theory must explain what exactly coherence is and what kind of comprehensive system a true proposition must cohere with. Their key assumption is that truth is a comprehensive system of interconnected statements or propositions. Their position thus does not define truth in terms of a correspondence relation between propositions and the non-propositional world, but rather in terms of systematic interconnectedness of propositions. Even so, many philosophers deny that every person's set of beliefs constitutes a truth-making system in virtue of systematic coherence. Many people have logically inconsistent sets of beliefs, and it is not plausible to hold that all the members of an inconsistent set of beliefs are true. A similar problem arises for the view that a particular community's set of believed propositions qualifies as a true-making system. In addition, it would not help to restrict the view to propositions agreed on by all the members of a community. We can imagine another community all of whose members agree on numerous opposite propositions. Of course, both sets of accepted propositions cannot be true.

A defensible coherence theory seems to need the requirement that the relevant comprehensive set of propositions must be intimately connected in some way with actual states of affairs. Otherwise, truth and knowledge will neglect the way the world actually is. So, it appears that coherence among propositions or beliefs is inadequate by itself for the sort of truth required by knowledge. Such coherence by itself may have nothing to do with what is factual, as we can see from a case of obviously far-fetched but coherent science fiction. Proponents of a coherence theory of truth must explain, then, the essential connection between coherence and how things are. The formulation of this explanation is a serious problem facing coherentism about truth.

Pragmatic value

Pragmatism about truth entails that to say that a proposition is true is to say that it is useful in a certain way. Pragmatist theories of truth emerge from William James^[18,19] and John Dewey,^[20] although Charles Peirce^[21] deserves credit for founding the philosophical movement called "pragmatism." James and Dewey emphasized that the kind of usefulness definitive of truth is not identical with what we ordinarily call "usefulness." The common theme of the pragmatist approaches of James, Peirce, and Dewey is that truth consists in a certain kind of validation of ideas, and that such validation

determines the "pragmatic" value of an idea. Even so, the resulting notion of cognitive usefulness, or validation, is not satisfactorily explained by Peirce, James, or Dewey. They sometimes seem to identify truth with a kind of verification. Specifically, they seem to hold that any proposition suitably conducive to a unified, or coherent, account of our experience qualifies as true. They evidently assume that such conduciveness to a unified account is constitutive of truth.

Some philosophers fault pragmatism about truth for confusing matters of justification (or, warrant) and matters of truth. They challenge pragmatists to explain why *false* propositions cannot have pragmatic value in virtue of their being useful in unifying our experience and even being accepted by all inquirers. The challenge for pragmatists is to give an account of the alleged necessary connection between what is pragmatically valuable, in virtue of verification, and what is factual. We ordinarily allow for validated beliefs that are, unknown to inquirers, not actually true. The history of science offers cases illustrating this point. Many comprehensive theoretical systems, including the Ptolemaic model of the universe, in fact include false propositions. So, it's unclear how to defend the view that cognitive usefulness is definitive of truth. Pragmatists have not offered a convincing case for a necessary connection between what has pragmatic value and what is factual.

Justification

Some true beliefs result just from lucky guesses and thus fail to qualify as knowledge. A groundless guess might be true, and even be believed by a person, but still would not be knowledge. Knowledge requires not only that a belief condition and a truth condition be satisfied, but also that the satisfaction of the belief condition be "properly related" to the satisfaction of the truth condition. This is one general way to characterize the justification condition for knowledge. *Epistemic*, or *cognitive*, justification is the kind of justification appropriate to true beliefs that qualify as knowledge. More specifically, a knower must have an *adequate indication* that a known proposition is true. Such adequate indication may be understood as *evidence* indicating that a proposition is true; we then have a traditional view of justification as evidence, as suggested by Plato and Kant, among others. This view entails that true beliefs qualifying as knowledge must be based on justifying reasons, or evidence.

Justified beliefs can be false, and this view is *fallibilism* about justification. It allows, for instance, that astronomers before Galileo could be *justified* in holding that the sun moves around the earth, even though their position is *false*. Justifying support for a proposition need not be such that necessarily if the justifying proposition is true, then the justified proposition is true too. *Inductive* justification does not logically entail a proposition

thereby justified. It obtains when, if the justifying support is true, then the justified proposition is *probably* true to some extent. In addition, epistemic justification is typically *defeasible* in that justifying support for a proposition for a person can cease to be justifying for that person when that person acquires additional evidence. Your justification, for example, for thinking that there is a large flower display in the corner of the museum can be defeated by new evidence acquired upon your noticing that a holographic image of a flower display is being projected into the corner.

According to many epistemologists, our beliefs about the external world, including our beliefs about household physical objects, are justified nondeductively, probabilistically, fallibly, and defeasibly. There is, however, a skeptical problem that confronts such claims of justification. This problem takes the form of a regress argument that prompts the question of whether, and if so how, we are justified in holding any belief entailing the existence of an external world *on the basis of other beliefs*.

An example will help. While strolling along the Pacific Ocean, we decide that surfing would be refreshing, but that the risks of surfing are serious today. Our belief that surfing is dangerous today receives support from other beliefs we have. We believe, for instance, that: 1) local weather reports predict dangerous ocean waves in our area today; 2) there are formidable waves already in our sight; and 3) the local weather reports and the presence of the formidable waves are reliable indicators of dangerous waves in the very near future. Our belief that surfing now is dangerous gets support from our belief that (1), (2), and (3) are true. Other beliefs we have will provide support for (1), (2), and (3) for us, thus, continuing the chain of inferential justification. Part of the support for (1) might be that (4) we talked with our friends about today's weather reports. Part of the support for (2) might be our belief that (5) we apparently see formidable waves nearby. Our support for (4) and (5) might be likewise inferential; so, the chain of inferential justification continues.

Skeptics will ask how our allegedly justifying beliefs for a belief in an external object are themselves justified. If they are justified by still further beliefs, how are those beliefs justified? We seem faced with an endless regress of required justifying beliefs, and such a regress seems too complex to employ in our actual everyday reasoning. So, we have a couple of options: either to accept the skeptical conclusion that inferential justification is unavailable or to explain how to handle the threatening regress. Epistemologists have offered three prominent approaches to the regress problem: coherentism, foundationalism, and contextualism.

Coherentism

Epistemic coherentism implies that all justification is inferential in virtue of "coherence relations" among

beliefs. Inferential justification, according to epistemic coherentism, ends in a system or network of beliefs with which the justified proposition coheres. Epistemic coherentism, being a coherence theory of justification, is not a coherence theory of *truth*. Coherentism about truth, as noted previously, aims to specify the meaning of "truth" or the essential nature of truth. A coherence theory of justification, in contrast, seeks to explain the kind of justification appropriate to knowledge.

Epistemic coherentists must explain, first, what kind of coherence is essential to justified belief, and, second, what kind of belief system a justified belief must cohere with. Many coherentists acknowledge logical entailment and explanation as typical coherence relations among beliefs. Explanatory coherence relations obtain when some of one's beliefs explain why some other of one's beliefs are true. My belief that it is thundering outside, for instance, might effectively explain the truth of my belief that my cat is running for cover. Of course, not just any belief system will confer epistemic justification, since some belief systems, such as those consisting of science-fiction propositions, are clearly erroneous and thus unable to confer epistemic justification.

According to the *isolation objection*, epistemic coherentism entails that one can be justified in believing empirical propositions that are incompatible with, or at least improbable given, one's total empirical evidence, includes one's non-propositional, sensory experiences. Such sensory experiences are non-propositional, and thus cannot be included in a belief system that confers justification. Epistemic coherence theories make justification depend just on coherence relations among propositions one believes or accepts, and therefore neglect the evidential significance of the non-propositional contents of nonbelief sensory states. Proponents of coherentism have not offered a cogent answer to the isolation objection.

Foundationalism

Epistemic foundationalism states that epistemic justification has a two-tier structure, given that some instances of justification are non-inferential, or foundational, and all other instances of justification are inferential, or non-foundational, in deriving ultimately from foundational justification. This structural view occurs in Aristotle's *Posterior Analytics* as a view about knowledge, and it receives an extreme statement in Descartes's *Meditations*, where it joins with the assumption that foundations of knowledge must be certain. Foundationalism is represented, in one form or another, by Russell,^[22] Lewis,^[23] and Roderick Chisholm,^[24] among many others.

Versions of epistemic foundationalism differ on the explanation of non-inferential, foundational justification, and on the explanation of how justification is transmitted from foundational beliefs to non-foundational beliefs. Some foundationalists, following Descartes, have assumed

that foundational beliefs must be indubitable or infallible. They embrace *radical* foundationalism, the view that foundational beliefs must be certain and that such beliefs must guarantee the certainty or the truth of the non-foundational beliefs they support. Such foundationalism is now unpopular, because very few, if any, of our perceptual beliefs are certain, and the beliefs that might be candidates for certainty (e.g., the belief that I am now conscious) are insufficiently informative to guarantee the certainty or the truth of our highly specific inferential beliefs concerning the external world, including beliefs from physics, chemistry, and biology.

Modest foundationalism, favored by most contemporary foundationalists, implies that foundational beliefs need not possess or yield certainty and need not deductively support justified non-foundational beliefs. A *non-inferentially justified, foundational* belief is a belief whose epistemic justification does not derive from other beliefs, regardless of whether the *causal* basis of foundational beliefs includes other beliefs. Modest foundationalists have characterized non-inferential, foundational justification as: 1) self-justification; 2) justification by nonbelief, non-propositional experiences; or 3) justification by a reliable nonbelief origin of a belief. Recent proponents of self-justification have included Chisholm^[24] and Ducasse,^[25] who hold that a foundational belief can justify itself, apart from any evidential support from something else. In contrast, proponents of foundational justification by nonbelief experiences reject literal self-justification, and hold, following Lewis,^[23] that foundational perceptual beliefs are justified by nonbelief sensory or perceptual experiences (e.g., my nonbelief experience involving seeming to see a pomegranate) that either make true, are best explained by, or otherwise support those foundational beliefs (e.g., the belief that there is, or at least appears to be, a pomegranate here). Proponents of foundational justification by reliable origins claim that non-inferential justification depends on nonbelief belief-forming processes (e.g., perception, memory, and introspection) that are truth-conducive to some extent, in virtue of tending to produce true rather than false beliefs. Such *reliabilism* invokes, as a justifier, the reliability of a belief's nonbelief origin, whereas the previous view invokes the particular sensory experiences underlying a foundational belief. Modest foundationalists typically agree that non-inferential justification can, at least in most cases, be defeated upon expansion of one's justified beliefs.

Foundationalists must explain the necessary and sufficient conditions for non-inferential justification and for the transmission of justification from foundational beliefs to inferentially justified, non-foundational beliefs. Modest foundationalists acknowledge nondeductive connections that transfer justification, but they have not reached agreement on the exact nature of such connections. Some modest foundationalists hold that a kind of "inference to a best available explanation" can account for transmission of

justification in many cases. The belief, for example, that there is a red pomegranate before me can, in my current circumstances, provide a best available explanation of various foundational beliefs about my perceptual inputs. This, however, is a controversial matter among contemporary foundationalists.

Contextualism

Wittgenstein^[26] suggested a central thesis of contextualism with his claim that "at the foundation of well-founded belief lies belief that is not founded." If Wittgenstein is claiming that at the foundation of justified beliefs lie beliefs that are unjustified, we have an alternative to coherentism and foundationalism. According to contextualism, in any context of inquiry, people simply assume (the acceptability of) some propositions as starting points for inquiry.^[27] These "contextually basic" propositions themselves lack evidential support, but can nonetheless support other propositions. Contextualists emphasize that contextually basic propositions can vary from social group to social group and from topical context to topical context, for example, from moral inquiry to physical inquiry. What functions as an unjustified justifier in one context need not in another context.

Contextualists must explain how epistemically unjustified beliefs can provide epistemic justification for other beliefs. They need to avoid the implausible view that just *any* unjustified belief, however obviously false or contradictory, can yield justification in certain contexts. If just any unjustified proposition can serve as a justifier, we shall be able to justify any proposition we want. Even if we typically take certain things for granted in certain contexts, this does not underwrite the view that there are unjustified justifiers. The things typically taken for granted may actually be supportable by good reasons. If they are not, we need some way to distinguish them from unjustified beliefs that cannot transmit justification to other beliefs. Contextualists must explain, then, how an unjustified belief, but not just any unjustified belief, can confer inferential justification on other beliefs, but they have not reached agreement on the needed explanation.

Some recent philosophers have rejected the traditional justification condition for knowledge. Some of these philosophers recommend a *causal theory of knowing* according to which you know that *P* if you believe that *P*, *P* is true, and your believing that *P* is *causally produced and sustained* by the fact that makes *P* true. One can develop such a causal theory in various ways, but one will need to give special attention to knowledge of universal propositions. Perhaps I know, for example, that all encyclopedia entries have been written by humans, but my believing this seems not to be causally supported by the fact that all encyclopedia entries have been written by

humans. It is doubtful that the latter fact produces any of my beliefs. We need, in any case, a careful explanation of how a causal theory can account for knowledge of such universal propositions.

Fourth Condition

Contemporary epistemologists have no widespread agreement on what precisely the key components of knowledge are, even if there is a considerable agreement that knowledge requires justified true belief. Traditionally, many philosophers held that justified true belief is logically sufficient as well as necessary for knowledge. This is a minority position now, owing mainly to “Gettier counterexamples” to this view. Edmund Gettier^[28] published a challenge to the view that if you have a justified true belief that *P*, then you know that *P*. One of Gettier’s counterexamples is:

Smith and Jones have applied for the same job. Smith is justified in believing that (a) Jones will get the job, and that (b) Jones has ten coins in his pocket. On the basis of (a) and (b) Smith infers, and thus is justified in believing, that (c) the person who will get the job has ten coins in his pocket. As it turns out, Smith himself actually gets the job, and he happens to have ten coins in his pocket. So, although Smith is justified in believing the true proposition (c), Smith does not know that (c).

Gettier-style counterexamples are cases where one has a justified true belief that *P* but lacks knowledge that *P*. The Gettier problem is the challenge of finding a modification of, or an alternative to, the traditional justified-true-belief analysis that avoids Gettier-style counterexamples. After four decades of vigorous research, contemporary epistemologists have not produced a widely accepted solution to the Gettier problem. Even so, many epistemologists take the main lesson of Gettier-style counterexamples to be that propositional knowledge requires a fourth condition, beyond the justification, belief, and truth conditions. The importance of the Gettier problem stems from the importance of our having a precise understanding of the nature, or the essential components, of propositional knowledge. A precise understanding of the nature of knowledge requires a Gettier-resistant account of knowledge.

CONCLUSION

Our familiar concept of knowledge resists easy analysis, but it does have some identifiable components. We do well, however, not to demand more precision of this concept than is available. Philosophers, in particular, will benefit from attention to that lesson.

Knowledge Creation and Use in Organizations

Maija-Leena Aulikki Huotari

Anna Suorsa

University of Oulu, Oulu, Finland

Abstract

The entry provides an overview of knowledge creation and information use within the organizational context. It is claimed that research focusing on these issues has developed since the 1990s within library and information science (LIS). Research on information use within organizational settings belongs to the research field of information behavior and information seeking and has gained attention in research focusing on information needs and uses of different professions and tasks and recently on outcomes or effects of information. Research on knowledge creation, in turn, is related to the multidisciplinary field of knowledge management (KM) and has been more focused on within the field of organization theory and management studies. In this entry, first, the distinctive nature of the concepts of information and knowledge is highlighted, and the main types of organizational knowledge are presented. Information management (IM) and KM as the fields of LIS and their research traditions are discussed. Research on information use is reviewed by placing the emphasis on information use environments in particular. Moreover, a model of organizational information use that includes knowledge creation is examined, and the Japanese models of knowledge creation are presented. These models are compared to highlight their potential relationships. After that, an alternative framework will be presented as a theoretically consistent foundation to understand knowledge creation in organizational settings. Finally, future research trends are outlined.

INTRODUCTION

Knowledge creation and use within organizational settings is quite a recent phenomenon in library and information science (LIS) research but emphasized by multidisciplinary research on knowledge management (KM) since the mid-1990s. However, the conceptual base of KM research has caused quite a deal of debate about the legitimacy of KM as a research field of LIS. This debate is based on the terminological confusion related to the concepts of information and knowledge. For example, often the concepts of information use, knowledge use, and knowledge utilization are used as synonyms. It has even been argued that the phenomenon that is referred to as KM in other fields of science refers to information management (IM) in LIS.^[1] To avoid the terminological confusion in this entry, the foci are on the creation of knowledge and the use of information within the organizational context. First, the differences of the concepts of information and knowledge are examined, and the main types of organizational knowledge are outlined. Second, the research traditions of IM and KM are discussed. Third, research on information use and the idea of information use environments and a model of organizational information use that includes knowledge creation are examined. Fourth, the Japanese models of knowledge creation are shortly reviewed. This is followed by a comparison of these models to indicate their main relationships. After that, an alternative framework is presented as a theoretically

consistent foundation to understand knowledge creation in organizational settings. In the “Conclusion,” some future research trends are outlined as well.

CONCEPTIONS OF INFORMATION AND KNOWLEDGE

Information and knowledge are closely related concepts. However, they are not synonyms. Research on LIS has widely utilized Claude Shannon and Warren Weaver's^[2] information transfer model, which treats information as a entity that can be transmitted through a channel. This is called an objective view of information. From the cognitive viewpoint, in turn, knowledge refers to something that resides in human mind. In this conception, knowledge is an outcome of information that is interpreted and internalized and thus becomes a part of the person's existing knowledge structure.^[3] This implies that internalized information also gives a new shape or form to the person's knowledge structure. In fact, the etymology of the word information as “informatio” in Latin refers among other things to the act of giving a form to something (Capurro and Hjørland,^[4] p. 351). From the cognitive viewpoint, this refers to learning, too. This is called the subjective view of information. Moreover, in LIS, information has been defined as information-as-thing (referring to, e.g., a document), information-as-process

(referring to becoming informed), and information-as-knowledge.^[5]

Knowledge is often understood to consist of explicit, implicit, and tacit elements. In the mid-1990s, the Japanese researcher Ikujiro Nonaka and his colleagues' theory of knowledge creation, the so-called SECI model, popularized the Hungarian scientist Michael Polanyi's^[6] identification of the tacit nature of knowledge.^[7,8] Tacit knowledge is the most intangible and very personal form of knowledge in organizations and thus difficult to articulate and formalize. However, many authors argue that tacit knowledge is understood too superficially in the conceptions of KM^[9] when actually referring to implicit knowledge.^[10,11] It has even been claimed that Nonaka has misused the concept of tacit knowledge as Polanyi's idea of *tacit knowing* refers to the most personal knowledge that cannot be expressed verbally.^[1]

The concept of organizational knowing and its management is based on the assumption that information and knowledge are something social by nature. For example, the constructionist viewpoint regards knowledge as a social construct assuming that tacit knowledge is manifest in organizational practices. Knowledge creation and innovation can be viewed as "a generative dance" and an outcome of the interplay of knowledge and knowing.^[12] Moreover, it has been claimed that cognition and action are inseparable that makes articulation of tacit knowledge unnecessary.^[11] Knowledge can also be viewed as a collection of processes that allow learning to occur and knowledge to be internalized within a social community.^[13] This view relates to the idea of a community of practice as "groups of people informally bound together by shared expertise and passion for a joint enterprise—engineers engaged in deep-water drilling, for example, consultants who specialize in strategic marketing, or frontline managers in charge of check processing at a large commercial bank... Instead of being composed primarily of people working on their own, they often exist within larger organizations"(Wenger and Snyder,^[14] pp. 139–140).

Even the five types of organizational knowledge, namely, embrained, embodied, encultured, embedded, and encoded, are claimed to be insufficient to account for knowledge as a social process.^[15] Moreover, it has been suggested that the evolution of knowledge forms a social learning circle: through the codification of shared experience, personal knowledge can become proprietary knowledge or the intellectual capital of an organization. Once externally scrutinized, this knowledge becomes public, while widely internalized, it turns to common sense.^[16] The assumption that knowledge exists in human minds makes it hard to manage causing much debate about the relevance of the concept of KM. Therefore, we can claim that the management of people is crucial when aiming at the management of knowledge and information as a resource. Thus the structure of an organization among

other enabling factors becomes the main focus of managerial activities when aiming at enhancing knowledge creation throughout the organization and beyond its borderlines.^[17]

RESEARCH TRADITIONS OF IM AND KM

Research on IM and KM are quite recent phenomena in LIS. IM research has its roots in the beginning of industrialization,^[18] though widely applied in practice as information resources management (IRM) since the 1970s as an outcome of introducing and utilizing computers and automatic data processing to manage paperwork in public enterprises. KM research has its roots in the visions of information society and knowledge-based economy^[19], which strives for innovations. Innovations, in turn, are based on knowledge creation. The multidisciplinary field of KM research emphasizes the enhancement of an organization's innovative capability and the ability to create new knowledge and has gained wider interest since the mid-1990s. KM research can be viewed, for example, as four different discourses, namely, a neo-functionalist, a constructivist, a critical, and a dialogic discourse. The main argument in this view is that the nature of knowledge including its tacit dimension is understood differently in these four research traditions. The neo-functionalist discourse treats tacit knowledge in a separable form from explicit knowledge, and similarly does the critical discourse, which treats tacit knowledge as power. The constructivist discourse, in turn, does not separate tacit from explicit knowledge and comes close to Polanyi's idea of tacit knowing, and the dialogic discourse treats tacit knowledge as deeply internalized consisting of normalizing judgments.^[20]

In LIS we can make a clear difference between research on IM and KM. Research on IM is most interested in the use of information technology (IT) and information systems (IS) to manage organizational information resources. Besides different discourses, we can identify multiple research traditions within the multidisciplinary field of KM, for example, IT and management information systems (MIS), organization theories, and education science and learning theories. The first research tradition refers to the use of IT and IS to manage organizational information and knowledge and, thus, comes very close to IM within LIS. The second KM research tradition understands information and knowledge as social phenomena by nature and aims at enhancing organizations and their environments to support knowledge creation, also often called as knowledge construction or generation. The second research tradition has its roots in organizational theory and social and educational sciences, whereas the first tradition is based more on the computer science's point of departure. Also LIS has two research traditions, that is, the social sciences and humanities-based library science, or

information studies, and information science that is more oriented toward computer and information processing and cognitive sciences. Therefore, we can view KM as a field of LIS from these two ontological and epistemological viewpoints too.

From the LIS viewpoint, it is important to increase understanding of information and knowledge as resources due to their partly intangible nature. This development is supported by the resource- and knowledge-based views of an enterprise (e.g., Barney^[21], Grant^[22], Penrose^[23]) and the idea of organizational learning.^[24] As the value of information and knowledge resources is difficult to estimate in economic, quantitative terms,^[9] it is necessary to have a holistic view of how to combine human, technological, and structural factors in a unique manner to prolong strategic capability and sustainability. The core capabilities are created through activities consisting of values and norms, skills, and managerial and physical systems,^[25,26] and knowledge creation occurs by combining people's distinct characteristics with a particular set of activities.

RESEARCH ON INFORMATION USE

With regard to LIS, rigorous research on information seeking and use focusing on library collections and users' interaction with them was initiated in the late 1930s.^[27] Besides involving library users, these studies have later focused on information needs and uses of professionals such as scientists, engineers, managers, or civil servants. Quite often, these studies have been based on the positivist survey tradition typical in sociological research of the Chicago School in the United States. This system-oriented view is based on the conceptualization of information as an entity. An opposite, user-oriented view^[28] is based on the conceptualization of information as a process and as knowledge. In other words, information is regarded as a construct that is subjectively created in the mind of its user (see, e.g., Todd^[29], Savolainen^[30]). Moreover, the phenomenon of information use can be viewed from the macro and micro perspective. In this entry, the focus is placed on the macro perspective by examining the ideas presented by Robert S. Taylor and further elaborated by Chun Wei Choo.

Information Use Environments

Within LIS, Robert S. Taylor's research on information use is perhaps the most well known. Taylor's^[31] point of departure is complementary to the system-oriented, technology-driven, and content-driven views of IS design. Taylor states, "These conventional approaches need to be tempered and informed by a third approach that looks at the user and the uses of information, and the contexts within which those users make choices about what

information is useful to them at particular times. These choices are based, not only on subject matter, but on other elements of the context within which a user lives and works" (Taylor,^[31] p. 218). This means that the environment where information is used impacts on information flows and uses and also determines the criteria used to assess the value of information.

Taylor defines information behavior as the sum of activities through which information becomes useful and states that information behavior differs in different groups. The elements of information use environments are the following: sets of people, which include professions (e.g., lawyers, engineers, social workers), entrepreneurs, special interest groups (e.g., hobbyists), and special socioeconomic groups (e.g., elderly); problem dimensions, which refer to typical problems for these groups; work settings and embedded factors that refer to influencing attitudes toward information, information flows, and types and structures of required information; and problem resolution assumptions. Taylor suggests that his model is applicable to a variety of contexts. He claims that the final determiner of information value is the user who is in a particular context and develops criteria on information value from that context.^[32] Furthermore, he points out that it is important to take into account that different sets of people perceive information differently, which means that information may have different interpretations according to the context, and in the processes by which it becomes useful. Therefore, better understanding of the less rational factors affecting decision processes should be gained too.

General Model of Organizational Information Use

Chun Wei Choo^[33] has applied Taylor's model of information use environments, Dervin's^[30] situation-gap-model of sense making, and Kuhlthau's^[34] information search process, which includes the affective dimension, to a general model of information use within organizational settings. Choo's idea of information use embraces information seeking covering the thoughts, feelings, actions, and the environment in which these are played out. He contends that organizations use information on three arenas: to make sense of the environment in which they operate, to create or generate new knowledge, and to make decisions. Choo's thesis is that these interconnected processes provide a holistic view of organizational information use and form the essence of a knowing organization. The three modes of information use of a knowing organization consist of sense making based on the idea of an enacting organization,^[35] knowledge creating based on the idea of a learning organization,^[36] and decision making based on the idea of a rational organization.^[37]

Choo's model is concerned with information use at three stages: information needs, information seeking, and information use. For Choo, information seeking (as a part of information behavior) is a human and social process

through which information becomes useful. This assumption is based on Taylor's conception of information use as the individual making a choice or selecting messages from a larger pool to attend to or to act on. Information use implies the selection and processing of information in order to answer a question, solve a problem, make a decision, negotiate a position, or understand a situation. This also makes the relevance of information important and refers to the pertinence of information as a term used to describe the capability of information content to satisfy more personal information needs. Pertinence, a concept also incorporated in Kuhlthau's information search process model, integrates cognitive and affective needs and addresses demands of a particular situation in which the information need emerges.

In Choo's model, the definition of information uses is based on Taylor's^[31] classification of the types of uses as follows: enlightenment referring to the development of a context or making sense of a situation; problem understanding; instrumental; factual; conformational; projective; motivational; and personal or political use. These different types of uses are generated by the need perceived by users in particular situations. The model also highlights constructed, situational, and dynamic properties of information use.

Moreover, Choo examines information use in organizational sense making, knowledge creation, and decision making. In sense making, information is used to reduce ambiguity and to develop shared meanings for taking collective actions. However, organizations also maintain a certain level of information equivocality and accommodate a diversity of interpretations. In knowledge creation, Choo draws on three types of organizational knowledge: explicit, tacit, and cultural, and on Nonaka's SECI model and its extension, as well as on Normann and his colleagues^[38,39] (see also Huotari and Iivonen^[17]) ideas on knowledge processes as the basis for organizational knowledge creation. He describes information needs, seeking, and use on knowledge creation through cognitive needs, affective responses, and situational dimensions. For Choo, knowledge creation includes the modes of knowledge conversion (SECI; Nonaka and Takeuchi^[8]), knowledge building,^[25] and knowledge linking (e.g., Wikström et al.^[39]).

KNOWLEDGE CREATION

It is widely accepted that knowledge creation is a social phenomenon, but theoretical research of this phenomenon is quite limited. The examination of Choo's model of organizational information use in the previous section also highlights phenomena related to knowledge creation. The Japanese models of knowledge creation provide further insights about knowledge creation within organizational settings. The most well-known among these models were

presented by Ikujiro Nonaka and his colleagues Hirotaka Takeuchi, Ryoko Toyama, and Noboru Konno during the 1990s and the beginning of this millennium.

Nonaka has criticized the notion of the organization as an information processing system and, instead, stressed a holistic and dynamic view of the organization that creates new knowledge through interaction. Nonaka and his colleagues' views are based on the idea of the social nature of information and knowledge and the dynamic nature of the organization, its activities, and the environment. They state that "Knowledge creation is a continuous, self-transcending process through which one transcends the boundary of the old self into a new self by acquiring a new context, a new view of the world, and new knowledge. . . knowledge is created through the interactions amongst individuals or between individuals and their environment. . . An individual (micro) influences and is influenced by the environment (macro) with which he or she interacts" (Nonaka et al.,^[40] p. 8). With the organizational knowledge creation, they mean ". . . the capability of a company as a whole to create new knowledge, disseminate it throughout the organization, and embody it in products, services, and systems" (Nonaka and Takeuchi,^[8] p. viii). Nonaka and his colleagues' models of organizational knowledge creation are shortly reviewed in the following sections.

SECI Model

One of the first models of knowledge creation is the so-called SECI model or the SECI process, which is based on the notion of conversion of knowledge between its tacit and explicit types through four phases: socialization, externalization, combination, and internationalization. Though the SECI model has been criticized, it is also widely used to describe the social aspects related to knowledge creation.

The SECI model implies spirals from one ontological level to the next, for example, from the level of an individual to the level of a group. Nonaka and Takeuchi drew on the ideas of tacit knowledge suggested by Polanyi and the idea of mental models. In addition, tacit knowledge consists of technical elements and know-how. In socialization, the members of a work community share and transfer their experiences in tacit form when working together in practice or when socializing in an informal manner and thus create new tacit knowledge. Interaction is crucial at this phase and face-to-face interaction enhances socialization, which can occur beyond organizational boundaries. In externalization tacit, personal knowledge is converted by articulating it to explicit form by using, for example, metaphors, analogies, mathematical formulas, or models. This is seen as a critical phase in the knowledge creation process because the externalized, conceptualized knowledge forms the basis for new knowledge to be created. Communication is essential and group work techniques

can be utilized. At the combination phase, new, externalized knowledge is combined with the existing explicit knowledge. Techniques, methods, and means, including modern ICT, of interaction can support communication. This phase can also be used to operationalize concepts, for example, a vision into business or product concepts. In the internalization phase created, new explicit knowledge is converted to tacit knowledge. At this phase, all people involved in the knowledge creation process reform what they have already known. This is related to learning by doing as they internalize the created new knowledge to become a part of their daily activities and embedded in organizational routines. Interaction and collaboration of the members of the work community are essential and, for example, self-organizing teams or work groups can enhance internalization.

Models of Organizational Knowledge Creation

The SECI model was further developed by Nonaka and Takeuchi toward a model of organizational knowledge creation involving a wider range of issues and ontological levels, that is, the individual, the team or group, the department or the division, the organization, and the networks, and the definition of the factors that enable knowledge creation. This model consists of five phases, namely, sharing tacit knowledge, creating concepts, justifying concepts, building an archetype, and cross-leveling knowledge. Nonaka and Takeuchi define the enabling factors as organizational intention, that is, “an organization’s aspiration to its goals” (Nonaka and Takeuchi,^[8] p. 74), autonomy, fluctuation and creative chaos, information redundancy, and requisite variety. Moreover, they stress flexibility in acquiring, interpreting, and relating information and claim that love, care, trust, and commitment enhance interaction, communication, and knowledge creation.^[8]

As knowledge creation is essential to sustain an organization’s innovative capability and strategic position in the marketplace, it must be in line with the strategic vision and goals set. The unified model of knowledge creation presented by Toyama, Konno, and Nonaka^[40] incorporates into the knowledge vision the SECI process, the shared context of knowledge creation called Ba, and the knowledge assets. The knowledge vision directs the relations of these three main elements and defines what kind of knowledge should be created at different sectors of activity and also how the organization and its knowledge base are developed with time. The knowledge vision also defines the values and norms that are used to determine how created new knowledge is assessed and valued, that is, how important new knowledge is for gaining the strategic goals.

The idea of Ba is based on the concept of Basho introduced by the Japanese philosopher Kitaro Nishida in the 1920s. Ba refers to time, space, and place where

information is interpreted to become knowledge. Locationality and simultaneous incorporation of space or place and time and mental state of mind are typical for Ba; in other words, Ba can be an office, a virtual space for working, and the state of mind. By localizing and activating organizational members to interaction, Ba enables knowledge conversion from tacit to explicit and from individual to collective. Moreover, by transcending the boundary between micro and macro for interactions at different levels, Ba can amplify the knowledge-creating process.

The SECI model and the four types of Ba, namely, originating, dialoguing, systemizing, and exercising, are linked, and they interact to create knowledge assets of four types. Experimental knowledge assets consist of shared tacit knowledge that is based on organizational members’ and stakeholders’ shared experience and thus are difficult to conceptualize, copy, or imitate. Conceptual knowledge assets are based on symbolic and conceptual models, for example, product and brand characteristics. Systemic knowledge assets consist of organized explicit knowledge that is easy to store and transfer in digital IS. These knowledge assets are most visible, and they can be protected by patents. Routine knowledge assets consist of tacit knowledge that is embedded in organizational activities and practices. These knowledge assets include daily organizational routines, working culture, and climate. These four types of knowledge assets form the basis for the knowledge-creating process.

COMPARISON OF THE MODELS OF ORGANIZATIONAL INFORMATION USE AND KNOWLEDGE CREATION

The strength of Choo’s model is the holistic view provided by integrating in an interdisciplinary manner the previous research findings, theoretical models, and frameworks. The Japanese models provide a holistic and unique approach to knowledge creation within organizational setting. All models examined provide a macro perspective of organizational phenomena and pursue to incorporate information use to a wider context including the physical place and the mental state of the information user. In the Japanese models, the macro perspective is an extension of the micro perspective whose interaction is embedded in the processes of knowledge creation. Choo’s model focuses on organizational knowledge creation as one of the three aspects of organizational information use. In Nonaka and his colleagues’ model of organizational knowledge creation, in turn, the knowledge assets provide inputs for the knowledge creation processes and are their outcomes too. In the Japanese models, information use is related to interaction and communication through which information is interpreted into knowledge and embedded in practices. These models are based on the assumption of the collective and dynamic nature of organizational

knowledge creation and the transfer of individual knowledge to collective knowledge. These aspects are included in Choo's model through Robert S. Taylor's conception of the information use environments, as sets of people, work settings, problems dimensions, and their resolution assumptions, which are embedded in the context and provide a collective platform to interpret information. This context is very collective in nature and provides the criteria for judging the value and usefulness of information. In Nonaka and his colleagues' models, the essence of knowledge creation is based on the conversion of tacit and explicit knowledge through interaction between the individual, the organization, and its environment. This aspect is evident in the concept of Ba, which is the collective and shared context of knowledge creation where information is interpreted to become knowledge and create the four types of knowledge assets.

The strategic orientation of these models differs. In Choo's model, the strategic aspect is embedded in the idea of a knowing organization, which uses information through the interconnected processes of sense making and enacting the environment, creating knowledge through learning, and making decisions. In these processes, uses of information are characterized as constructed, situational, and dynamic. In Nonaka, Toyama, and Konno's model, the knowledge vision directs the three elements, namely, the SECI process, the Ba, and the knowledge assets, of organizational knowledge creation.

Alternative Framework to Understand Knowledge Creation

The model of organizational knowledge creation presented by Chun Wei Choo and the Japanese knowledge creation models reviewed in this entry have both their strengths and weaknesses. Nonaka's and his colleagues' models are the most well-known in the Western countries, but their work has been criticized, too. Besides critique toward the use of Polanyi's concept of tacit knowing, the fact that their ideas are culturally bound has been under scrutiny. Choo's idea of the knowing organization has not been under scrutiny to such an extent, though it is evident that it is demanding to indicate how consistent the model's conceptual basis is.

As an alternative to these models, a novel framework of knowledge creation is shortly presented by the authors of this entry. It is based on hermeneutic phenomenology, which provides a theoretically and conceptually consistent foundation for understanding the phenomenon of knowledge creation.^[41] By introducing a novel way to conceptualize the collaborative nature of knowledge creation, the framework clarifies the conceptual vagueness of research on KM. Thus, it also contributes to the debate on the relevance of the concept of KM as a field of LIS. The point of departure is hermeneutic phenomenology and Hans-Georg Gadamer's idea of hermeneutic

conversation.^[42,43] This allows examination of knowledge creation, which is started by defining the concept of a human being and focusing on the human existence in interaction—constantly creating and simultaneously being created when living in the world—and not on the concept of knowledge as such. In other words, the framework provides a definition of a human subject as a creator of knowledge, contrary to the models presented in this entry, in which the definition is taken for granted. Moreover, contrary to previous research on knowledge creation, this framework provides a thorough definition for the concept of interaction^[41] (see also von Krogh^[44]).

The thesis of this novel framework is that the conceptualization of interaction is dependent on the conceptualization of a human being. Knowledge creation is examined in the following three areas: structure of the interactive event as the hermeneutic cycle involving distanciation, anticipation, correction, and reassessment; construction of the human experience in interaction consisting of the temporal dimensions of past, present, and future; and modes of being in interaction, such as reflective, critical, and open ones (see also Suorsa^[45]). In this framework, interaction is regarded as a communal and shared experience, which demands total presence in the course of events. It is claimed that the framework's hermeneutic circle and phenomenological conceptualization of a human being provide a defined and coherent structure for understanding the event of knowledge creation as a future-oriented, conscious act of interaction.^[41]

CONCLUSION

This entry aimed at providing an overview of information use and knowledge creation within organizations. The examination was placed on the context of KM research in order to indicate how information use relates to knowledge creation within organizational settings. Choo's model of organizational information use and Nonaka and his colleagues' models of organizational knowledge creation were shortly reviewed and further compared to highlight their potential relationships. It can be concluded that these models are based on the ideas of the social and dynamic nature of knowledge and knowledge transfer from the individual to the collective through knowledge conversion between its tacit and explicit types. These models relate to the LIS and KM research traditions based on the social and educational sciences and organization theory, rather than to the computer and IS and cognitive sciences.

However, as the conceptual vagueness of research on KM has been a concern in LIS, a framework based on phenomenological hermeneutics is finally introduced by the authors of this entry as a theoretically consistent foundation to understand and clarify the conceptualization of the phenomenon of knowledge creation in organizational

settings. In this framework, the foci are on the conceptualization of a human being and interaction as the major elements of knowledge-creating events.

Future Trends

The phenomena addressed by research on KM seem to some extent emerge in the research agenda of LIS. As pointed out recently, research interests in information use and outcomes, effects, applications, or impacts of information have been increasing steadily.^[27] These should be linked with the aspects of knowledge creation or construction. Research on collective practices of information use and knowledge construction could be increasingly emphasized. Furthermore, research on the use of new Internet-based technologies including applications of social media and web 3.0 may extend the scope of inquiry toward strategic knowledge creation and information use within networked organizational settings at the global level. Moreover, introducing novel, ontologically and epistemologically consistent interdisciplinary, or even cross-disciplinary models and frameworks would be fruitful for investigating and further understanding this multidimensional organizational phenomenon.

Abstract

Knowing what to do with the massive amount of data collected has always been an ongoing issue for many organizations. While data mining has been touted to be the solution, it has failed to deliver the impact despite its successes in many areas. One reason is that data mining algorithms were not designed for the real world, i.e., they usually assume a static view of the data and a stable execution environment where resources are abundant. The reality however is that data are constantly changing and the execution environment is dynamic. Hence, it becomes difficult for data mining to truly deliver timely and relevant results. Recently, the processing of stream data has received many attention. What is interesting is that the methodology to design stream-based algorithms may well be the solution to the above problem. In this entry, we discuss this issue and present an overview of recent works.

INTRODUCTION

Knowing what to do with the massive amount of data collected has always been an ongoing issue for many organizations. Today, data are not just ingredients for churning out statistical reports, but are the basis of supporting efficient operations in many organizations. And to some extent, they provide the competitive intelligence needed to survive in today's economy. Since data can be potentially so important, it becomes increasingly difficult to refrain from collecting any data available. The effect of this is that organizations are overloaded with information.

Data mining has been touted to be the solution (or perhaps, the killer application) to the problem of information overloading. It is supposed to replace the human in performing the laborious task of sieving through data and to report only important results. In one sense, data mining technologies have created many successful stories and have in the recent years, gained research and industry interests. Yet, it does not seem to deliver the impact^[1] in terms of penetrating every aspect of life or systems (compared to, for example, the Internet).

There are many reasons for a lack of impact—such as human factors, technical issues, or a combination of both. On the technical issue, we believe conventional data mining algorithms (and hence their products) were designed with two wrong assumptions. First, it assumes that the data are static in all aspects. Second, it assumes that the execution environment where the algorithm runs is stable with abundant resources (e.g., memory or computing power). The reality however is that both assumptions do not hold in the context of the problems that we are trying to address.

First, most conventional data mining algorithms operate on a snapshot of the data. The data may be collected and stored in a data warehouse where during data mining, is assumed to remain static even though new data could have arrived, or parts of the snapshot may no longer be valid. And throughout the lifetime of the algorithm's execution, this snapshot is assumed to be a reflection of the real-world situation. In addition, the data are assumed to be constantly available while the algorithm runs, i.e., there is some unbound or huge storage space for the snapshot where the algorithm can read as many times as it needs. While this may not appear to be an issue, real-world data are often many times larger. And we are not talking about scientific data here.

In a single day, Centrelink, Australia's welfare agency, has more than 11 million page requests in their Web logs; Telstra, Australia's largest telecommunications company, produces 15 million mobile call records; American supermarket chain WalMart records 20 million sales transactions; and Google handles 150 million searches. For such massive amount of data, it would be difficult, if not impossible, to generate any results in useful time by running off-the-shelves algorithms—even when unbounded memory, storage, and CPU time are available. This is because existing algorithms are simply not designed to do so.

The other problem with conventional data mining algorithms is that they all assumed an execution environment with all the resources they need, and that all resources are available until the execution terminates. Although such assumption is common in other applications, data mining algorithms cannot have such luxury by the sheer amount of time it needs to complete a task. In some cases, this may be ongoing as data keep arriving. Hence, data mining

algorithms must be aware of the conditions of the host environment (e.g., unavailability of host, reduced resources, etc).

This awareness is becoming very important in today's computing paradigm. Conventionally, data mining is considered a specialized technology available to a limited number of organizations. They were often operated in a controlled and centralized environment, where the analysis involved an expert user. The conventional process of knowledge discovery follows a strict sequence and algorithms ran in batch modes. Nevertheless, progress in other technologies changed the paradigm.

Advancements in data storage and acquisition technologies, wireless and mobile technologies, the Internet, and smaller computing devices all contributed to this change. Huge amount of data can now be collected from multiple sources; wireless and mobile technologies created pervasive computing; the Internet gave rise to connectivity; and as a result, users can work across different devices. Most important of all, these technologies generate enormous amount of data that demand ongoing and real-time analysis.

For a while, data mining researchers overcame the problem by developing faster algorithms and incorporating

interactively into the knowledge discovery process. But the amount of data continues to grow exponentially compared to the efficiency of the algorithms. The gap between data mining and the real world enlarges. Very recently, the database community has recognized that the existing database approaches (including data mining) are no longer suitable for handling this class of data that arrives continuously at a very high rate. Because of its continuity, they are called data streams.^[2] New algorithms for processing and mining streams were proposed.^[3,4] In particular, the mining of stream data does not require a complete snapshot. All results are reflected as soon as possible when data arrive, and it can operate in host environments where resources are scarce. Despite the limited resources, the algorithm is able to compute very quickly using a small amount of CPU cycle. This speedup and lower resource consumption come at the price of lower accuracy in the results; but the error is maintained at a user-acceptable level.

To give a clearer picture of what we have discussed so far, Fig. 1 shows a timeline of a sequence of events occurring during data mining. The same data are analyzed by both conventional algorithms (in the upper half of the

Fig. 1 A comparison between conventional data mining algorithms and the new stream-based algorithm by looking at the sequence of events happening in the data. Also shown are two graphs depicting their resource consumption pattern.

figure) and stream-based algorithms (lower half). We first illustrate the example for the case when the conventional algorithm is used. Our hypothetical problem here is that we are interested in looking for interesting patterns. An interesting pattern in this case is defined as the occurrence of a symbol which we denoted as **T** in the Fig. 1.

As in the conventional case, a snapshot of the data is taken when the user begins data mining. In our example, the snapshot contains the symbols {**H, D, J, Y, U, E, R, P, ...**}. Once the snapshot is read, the algorithm begins processing using some sophisticated search technique which at some point in time, will usually consume a large amount of memory and CPU cycles as the graph at the top of the figure shows. During execution, data continue to arrive (usually at a rapid rate). In the snapshot approach, this newly arrived data may be stored somewhere until the next analysis is commissioned. As illustrated in our example, the interesting element was missed and the algorithm reported an outdated or invalid result.

To capture the interesting element, the next run of the algorithm can only start after it arrives and is captured in the snapshot. In real life, this would be impossible—because it is impractical to start instances of the algorithm at a regular intervals due to resource availability, and neither does it make sense to have a human observe the incoming data. Even if the element is captured in the snapshot, conventional algorithms may take too long to produce the results (recall that they operate in batch mode) rendering the discovery useless, or there is insufficient time to react.

On the other hand, the lower half of Fig. 1 illustrates what happens when stream-based algorithms are used. In this case, in place of the snapshot is a summary structure which holds only a subset of what a snapshot would contain. And once started, the algorithm constantly updates the summary structure whenever data arrive (so that it has the best picture of all data seen so far); but the size of the structure will always be bounded as shown in the second graph. Also, the CPU cycles consumed is much lower albeit with some possibility of error.

The error probability is generally outweighed by the overall benefits. We see that once the interesting element is detected, the algorithm is able to output this result usually before its value expires. This happens most of the time and is thus more useful. In the conventional case, the chances of missing the interesting pattern or finding it too late is very much higher due to a batch mode operation. Given the improved results and lower resource requirements, data stream techniques are popular in some unique data mining applications.

CHALLENGES IN DATA STREAM MINING

Applications that generate and/or consume data streams are found mainly in novel applications in the recent years.

This includes customer relationship management (CRM) applications,^[5,6] Web click streams,^[7,8] financial markets^[9,10] that retailed products on the Internet, telecommunication systems,^[9,11,12] and sensor networks.^[13,14] The data records generated by these systems are usually referred to as *transactional data streams*, and its data objects are often referred to as *transactions* or *data instances*.

Compared to traditional data sets, data streams are characteristically unique. First, it is unbounded in size compared to traditional data sets that are saved on storage devices limited by their capacity. Consequently, the infinite amount of data that needs to be consumed by any analytical algorithm is also limited by the amount of physical memory on the computing device. Since there is no persistent storage facility in that sense, algorithms have to process the data streams in an online fashion and in the order in which it arrives. This is where the challenges lie when designing algorithms for data streams—the order in which data objects arrived can neither be controlled nor can the algorithm have random access to the data. This gave rise to the well-known “one pass” requirement concept that is virtually nonexistent in algorithms for mining traditional data sets. Given these challenges,^[5,15] states that any knowledge discovery application in data streams should therefore meet the following criteria.

- **Transactions should be quickly processed in constant time:** As data streams are high in volume and are continuously generated at a high rate, it is impractical to revisit previous transactions or work through some data structures since then the processing time would be a function of some variable and thus, unreliable in high load situations.
- **Memory consumption should be independent of the stream size:** If the data stream is unbounded then no amount of memory would be sufficient. Algorithms for mining data streams therefore have to keep in mind that any design should utilize memory in a fashion that does not grow proportionally to the size of the data stream over the time.
- **Online access to data mining results:** In conventional algorithms, as in the scenario discussed earlier, the analyst would wait for the algorithm to complete before obtaining the results. In contrast, data streams are continuous and therefore, the algorithm does not terminate. While the algorithm is running, it is necessary that the user can have real-time access to the latest or intermediate analytics produced.
- **Analytics should reflect the state of the data stream:** Given that the analytics produced at any instance is a reflection of the data stream in the same instance, such a system should be capable of adapting to the changes in the data stream and produce the relevant analytics as discussed in the previous criterion. Preferably, the

system should also be capable of retrieving results at any instance of the data stream.

- ***Analytics should be a good approximate to actual results:*** In theory, the actual results would correspond to the results of conventional data mining algorithms been applied to a snapshot of the data stream been stored on a disk that is unbounded in size. While this exact result is often not necessary in data stream applications, the estimate produced under the above constraints should be a good reflection of the actual result. Otherwise, the analytics would be meaningless.

As a consequence of the above requirements, existing algorithms are no longer appropriate in the data stream setting. First, the assumption that data is available at any-time and that they can be read multiple times violates the “one pass” constraint. Second, the algorithms are not design to enable real-time queries. Therefore, changes in the underlying data stream could possibly invalidate the results. Unless human intervention takes place to rerun the analytics, existing algorithms do not have the means to automatically detect the changes and produce an updated set of results. These conventional algorithms include Apriori and FP-Tree in association analysis; k -means and k -centroid methods in clustering; and ID3 and C4.5 in classification.

Data Stream Management Systems

Of course, it would do injustice to the conventional data mining algorithms for not fulfilling the various data stream constraints since they exist in the context of a larger system such as a database management system (DBMS). When we take a system view to the problem, we see that the conventional algorithms were built on the legacy of DBMS design, where data queries are executed over a data store. On the other hand, data streams simply invalidated this mode of operation since it is infeasible to load the data stream into a data store, and have the queries executed in a similar fashion. This motivated the need for a data stream management system (DSMS),^[7,16] where the query operations and the relevant analytics have to be redesigned accordingly. The uniqueness of a DSMS can be effectively characterized by the following attributes.

- In a DSMS, data appear in transient streams and may not be stored persistently. This is in contrast to conventional databases, where data are placed in some storage device and retrieved through the execution of a query. Data objects in a transient stream however are processed in memory and discarded as soon as it was processed.
- In conventional database systems, the execution of a query will produce the exact result and the operation does not have a real-time constraint. Data stream

systems, however, have execution constraints such as processing cost and time. Hence, the results provided by the DSMS are usually an approximate.

- In data stream systems, a query is often not seen as a one-time operation. In other words, once executed, it runs continuously against the changing data stream and produces results (and updates) until the operation is cancelled by the analyst. In the current database environment, once the exact answer is obtained, the operation ceases. In the event that the data has changed, the operation is not executed until invoked by the analyst.
- In current database systems, data can be stored in any granularity and later retrieved for further operations. Again, this contrasts data stream systems, where data objects arrive at their finest granularity and only the summary of it is stored. With the DSMS, there is no way that the analyst can retrieve the original data objects in the data stream.
- In traditional database systems, performance can be optimized through a query plan that exploits the storage pattern of the physical database. This is not possible in data stream systems since the underlying stream is unpredictable. Therefore, query plans in DSMS are often hard to design in advance.

Suffice to say, these characteristics justified the need to reconsider how a data stream system is built. Unlike existing database systems, the DSMS requires a different set of techniques and operations. The essence of any data stream systems, given the difficult requirements, is the summary structure as discussed in our example. Therefore, the problem of designing a DSMS revolves around the techniques of summarizing the data to facilitate similar database queries on the data stream.^[16–18] In the sections that follow, we shall review some of these techniques.

Histogram

Histograms has been one of the most popular data reduction techniques.^[7,19] They use binning methods to approximate data distributions to minimize the information to be stored. The distribution of values in a bucket usually have a uniform spread assumption, i.e., the values are assumed to be at equal distance from one another. Hence, one only needs to store the minimum and maximum value, and the number of values in each bucket; and that provides a good summary about the original data values. For those values in the bucket, they can be easily approximated with good accuracy by the above arrangements.

We present some of the common histogram techniques^[20,21] below. In all these variants, data is partitioned into a certain number of β disjoint buckets (or intervals) B_j ($1 \leq j \leq \beta$); and the data distribution is represented as $T = (v_1, f_1), (v_2, f_2), \dots, (v_d, f_d)$, where v_i denotes a distinct value in T and f_i denotes the corresponding frequency.

- **Equi-width histograms:** Partition the data distribution into buckets such that the number of data points v_i in each bucket B_j is approximately uniform to the other buckets.
- **Equi-height histograms:** Partition the data distribution into buckets based on the summation of the frequencies. Generally, this value is the same for every bucket.
- **Maxdiff (Max difference) histograms:** Partition the data distribution such that the differences in frequencies between adjacent bucket boundaries are maximized.
- **V-optimal histograms:** If n_j is the number of entries in the j th bucket, $\bar{f}_j$ is the average frequency of that bucket, and $f_{j,k}$ is the frequency of k th entry in the j th bucket, then this technique partitions T such that $\sum_{j=1}^{\beta} \sum_{k=1}^{n_j} (\bar{f}_j - f_{j,k})^2$ is minimized. In other words, $\sum_{k=1}^{n_j} (\bar{f}_j - f_{j,k})^2$ is the variance of the j th bucket. Hence, a V-optimal histogram is the one with the least (smallest) variance of all histograms with the same number (β) of buckets.
- **Compressed histograms:** First store the most n ($n < \beta$) frequent values in n singleton buckets. The remaining values are then partitioned into $(\beta - n)$ buckets using equi-width or equi-height histograms.

Wavelet Transformation

Another technique for data summarization stems from a linear signal processing technique called discrete wavelet transformation (DWT).^[15,19] With DWT, one can transform a set of numerical values into a set of wavelet coefficients of the same length. The wavelet coefficients are then reduced by retaining only those values that are above a user-specified threshold. This creates a sparse representation that is well-suited for data reduction. The Haar wavelet is one of the simplest algorithms used in summarizing data streams.

Assume a data set $D = \{x_1, x_2, \dots, x_n\}$ with the size of $n = 2^k$. Then, the wavelet tree can be obtained as follows:

1. Let the original data set (also called input signal) be at level 0 in a wavelet tree.
2. At level 0, each pair wise average and difference of adjacent data points (x_{2i}, x_{2i+1}) is computed to produce the coefficients for level 1. Thus, $s_{0,i} = C \times (x_{2i} + x_{2i+1})$ and $d_{0,i} = C \times (x_{2i} - x_{2i+1})$; $0 \leq i \leq n/2$, where C is a predefined proportionality constant. The values $s_{0,i}$ constitutes a “smooth” (low-frequency) version of the signal, while the values $d_{0,i}$ represent the high-frequency content.
3. At level 1, the value of $s_{0,i}$ is used to compute the next level by repeating the previous step. This would give a smoother version of the signal, $s_{1,i}$ and $d_{1,i}$; $0 \leq i \leq n/4$.

4. The above is performed repeatedly at each level i to get the averages and differences at level $i + 1$ until the top level is reached, which has only one average and difference.
5. Finally, the coefficients are represented in a hierarchical form, including the average value at the top level, and the different values at all remaining levels.

Because the compressed wavelet coefficients can be used to easily reconstruct the original data set, they are often used to approximate queries^[22,23] and in data mining, for burst detection.^[14]

Sampling

In statistics, the idea of sampling is that a set of random samples is often a reflection of the original data set and thus captures the underlying characteristics using less resources. Therefore, sampling is a good way to summarize the data in question, or to process large databases.^[24,25]

Since most sampling techniques are applied on data sets with finite sizes, the unbounded stream makes sampling more challenging than it appears to be. In the data stream context, Viter's work becomes the fundamental solution to this problem. In Vitter,^[26] Viter introduced a number of algorithms to sample N records (without replacement) from a pool of N records, where the value of N is unknown a priori. Viter's algorithms were used by others^[27–29] with various degree of success.

To conclude our discussion of data stream systems, we briefly list some of the relevant projects undertaken in this area.

- **Aurora (Brown/Massachusetts Institute of Technology (MIT))** is a DSMS built for monitoring data streams. In Aurora (<http://www.cs.brown.edu/research/aurora>), the data streams are generated from sources such as sensors, satellites, or stock feeds. The DSMS tracks the data from numerous streams to detect abnormal activities and also produces summary (aggregation and reduction) and correlation reports.^[30]
- **STREAM** (<http://www-db.stanford.edu/stream>) is a DSMS project at Stanford University that investigates memory management issues, query processing,^[31] and algorithm design for mining data streams.^[32]
- **Cougar** (<http://www.cs.cornell.edu/database/cougar>) is a project by Cornell University to investigate query operations in sensor networks.^[33]
- **Hancock** is a project by AT&T. The project investigates the building of a domain-specific language, i.e., Hancock, to compute evolving profiles of their customers over telecommunication streams, stock market transaction streams, and credit card transaction streams.^[9,11]

- **NiagaraCQ** is a project at OGI/Wisconsin (<http://cs.wisc.edu/niagara>) focused on studying continuous queries over Internet XML streams. The project was motivated by the observation that many Web queries shared similar structures. The project exploits this observation to group queries in an attempt to reduce computational and I/O cost.^[34]
- **TelegraphCQ** is a Berkeley project (<http://telegraph.cs.berkeley.edu>) to develop a DSMS for querying in sensor networks. Much of the research issues investigated focuses on designing algorithms to run continuous adaptive queries over the data stream generated by the sensor network.^[35]
- **Traderbot** is a Web-based financial search engine (<http://www.traderbot.com>) that evaluates (both one-time and continuous) queries over real-time streaming financial data such as stock ticks or news feeds.^[7]

KNOWLEDGE DISCOVERY IN DATA STREAMS

So far, we have given an overview motivating the need for data stream applications; discussed the challenges that such applications face; and also the issues surrounding the design of data stream management systems, in which data mining facilities are a part of. In this section, we present some of the data mining algorithms designed for data streams. In doing so, we will provide the necessary background for the reader to compare the differences in the design of such algorithms against their conventional counterparts, and to appreciate how the data stream constraints are incorporated so as to develop other data stream algorithms in future data mining tasks.

Frequent Pattern Mining

Let $I = \{x_1, x_2, \dots, x_n\}$ be a set of items where $X \subseteq I$ is an itemset or pattern. Further, let $D = \{t_1, t_2, \dots, t_N\}$ be a database of transactions, where $t_i \subseteq I$ and N is the number of transactions in D . Given the minimum support $s \in (0, 1)$, a pattern X is a frequent pattern (or frequent itemset) if the support of X , i.e., $\text{supp}(X) = |\{X \subseteq t_i \in D\}|/N$, satisfies $\text{supp}(X) \geq s$.

The problem of frequent pattern mining in a transactional database is to find all frequent itemsets in D with respect to the given minimum support threshold s . Apriori is one of the most famous algorithm that is often used to uncover all frequent itemsets from transactional databases. By using Apriori, the number of times to scan a database can reach k or $k + 1$ times, where k is the size of the largest frequent itemset. This approach quickly becomes a significant issue in mining very large databases where the cost to scan databases is very expensive and time-consuming. To reduce mining cost, feature selection,^[36,37] parallel computing,^[38,39] and sampling^[25,40] has been used.

Among them, sampling is often the preferred technique by virtue of its simplicity.

Generally, once the load is shed to a manageable level where processing the incoming sampled stream is possible under the available processing resources, we can perform one of the three common frequent pattern mining activities.

Frequent item mining

Frequent item mining arose out of a variety of applications including network management systems, search engines, telephone call records, etc., where each generated instance corresponds to an item. In most of these applications, there are two issues to be addressed: 1) to find the top k frequent patterns; and 2) to optimize memory consumption during discovery. Most of the literature has solution in memory optimization through optimized counting techniques.

Let us consider an example of this problem in network management systems. In Demaine,^[41] an Internet Service Provider may be interested in monitoring a data stream of Internet Protocol (IP) packets to find the top k user's IP addresses which consume the most bandwidth. Such a query changes over time and given the speed at which IP packets are potentially generated in a large multiuser setting, this is where a one-pass frequent item mining algorithm is needed. The Simple algorithm proposed in Demaine^[41] (and also in Karp^[42]) was designed for such problems. Each transaction is seen to contain one data object, which in this case is the IP address, and the objective is to find those IP addresses which consume a certain amount of bandwidth (i.e., the threshold).

In the Simple algorithm, an array K of size $\lceil 1/s \rceil$ is used to count the frequent IP addresses, where s is the minimum threshold. Each element in the array K contains two fields: the item label (IP address) and the frequency count. When a new item arrives in the stream, look for it in K and increments the frequency count by 1 if found or otherwise, insert the item into K and initializing the frequency count to 1. Since K stores much lesser items than N , the number of unique items seen in the stream so far, K can become full. When that happens, the algorithm decreases the frequency count of all items by 1 and for those whose frequency value is zero, they are removed from the array. Clearly, the items in k at any time would be the superset of those frequent items since K 's size was determined by $\lceil 1/s \rceil$.

This straightforward algorithm is a good example of a design for data stream applications. The array size is bounded and fixed regardless of the size of the incoming data stream. In terms of memory consumption, the array size is very small compared to the memory utilization by conventional algorithms. Also, each incoming item in the stream only needs to be looked at once and the processing takes place on a fix time bounded by the maintenance of K against the incoming item. On the drawback, while the top

K frequent items are obtained at anytime against the latest state of the data stream, we observe that this algorithm is unable to accurately provide the actual frequency count from K . While the items in K is guaranteed to be the top K frequent items, the frequencies recorded is at best an approximation.

Frequent pattern (or itemsets) mining

Applications that generate transactional data streams are candidates for frequent pattern mining. These include Web click streams, e-commerce recommendation systems, and financial markets to name a few. Generally, the solutions for finding frequent patterns in data streams are extensions from algorithms for finding frequent items. Hence, most of these techniques are memory optimization methods. Needless to say, the memory issue is far more challenging in frequent pattern mining (compared to frequent item mining discussed in the previous section) due to the exponential increase of patterns to be tracked when the number of items increased linearly. As a result, it is difficult to determine the memory consumption in advance and thus force some research to estimate memory usage empirically.^[29,43,44]

The Lossy Counting-based algorithm reported in Manku^[29] was one of the first piece of work for frequent pattern mining in data streams. The algorithm uses a summary structure D containing a set of entries of the form (set, f, Δ) , where set is an itemset, f is the approximate frequency, and Δ is the maximum error probability. The data stream is divided into buckets of equal size w and processed in batches. Suppose the main memory contains β buckets, then Manku and Motwani's^[29] algorithm maintains D as follows.

For each entry in D , f is updated by counting the occurrences of set in the current batch. A new itemset is inserted into D if its frequency in the current batch of buckets satisfies $f \geq \beta$. An entry $(set, f, b_{\text{current}} - \beta)$ for the new itemset is thus created in D . Periodically, the entries that satisfy $f + \Delta \leq b_{\text{current}}$ are deleted from D . To ensure that the transactional stream is efficiently processed, the algorithm uses a number of implementation techniques. Specifically, there are three modules—the buffer, the Trie, and SetGen. The buffer repeatedly reads a batch of transactions into the available main memory while the Trie is used as the physical representation for D . The SetGen module operates on the current batch of transactions to find frequent itemsets. To handle variable sized transactions and to avoid explicit enumeration of all subsets in a transaction (which is extremely expensive), the algorithm uses a rule that a subset will be enumerated if and only if it occurs in the Trie or its frequency in the current batch exceeds β . This is why the algorithm needs as much memory as possible to process the data stream in batches.

The inherited drawbacks of Lossy Counting aside, the first drawback of Manku and Motwani's^[29] work is that to

reduce the number entries in D , β must be large since a small β value results in a large increase in the number of entries placed into D . Secondly, all available memory is used for buffering the transactions and hence, D has to be made a disk-based data structure. As a result, there is a major impact on the performance. Consequently, the solution is suitable only in situations where queries and analysis of the data streams are pseudo real-time. Later works however, e.g., Yu^[43] and Jin,^[44] did make improvements to this limitation.

Time changing frequent pattern mining

Given that data streams are constantly changing the state of the database, the patterns discovered at one instance may no longer be the ones that are frequent in the next instance. Unfortunately, most algorithms find all frequent itemsets and hence, process the data stream in batches. In other words, the transactions are buffered and the discovery takes place on the buffered transactions. When the next set of transactions overflow the buffer, it triggers the algorithm to replace the existing frequent patterns with the ones recently discovered. In this mode of operation, real-time processing is absent and results are not timely. In situations where the patterns can change quickly over time, the buffer approach fails.

FP-Streaming^[45] is an example of an algorithm that finds frequent patterns with respect to the time parameter. The frequent patterns obtained by a query is time-sensitive in the sense that the analyst can query for frequent patterns between arbitrary time intervals. Central to the algorithm is the maintenance of a data structure call FP-Stream which is an extension of the FP-tree structure.^[46] FP-Stream includes two components: a pattern tree and a tiled-time window. Instead of representing transactions like FP-tree, the pattern tree stores patterns where each node in the pattern tree represents an itemset including all items from the root node to the current node. The tiled-time window at each node maintains the frequency count of the corresponding itemset at different periods of time. The FP-Stream structure is maintained over the lifetime of the data stream.

Over a period of time T , the frequency of a pattern is counted. Since the pattern may be frequent in one time period T_i but not in a longer period T_j ($T_i \subset T_j$), the logarithm tiled-time window is used to store the frequencies of a node at different granularities of time. For example, the frequency of a pattern X would be stored as $f(n, n); f(n-1, n-1); f(n-2, n-3); f(n-4, n-7)$, and so on. Hence, the number of levels at each node is relatively small ($\log_2(n) + 1$). Next, the data stream is divided into batches of transactions $B_1, B_2, \dots, B_n, \dots$, where B_n is the latest batch. Patterns are computed whenever a batch B_i arrives. Each pattern is used to find a node in the pattern tree and the frequency updated in the tiled-time window. At the node, the frequency counts are shifted to the next window

to make space for the update or if all the windows are full, merging of the counts occur before saving the latest count.

Given that the above has to be done for all possible patterns, memory consumption is a concern and so the algorithm does housekeeping of the pattern tree from time to time. This is done by deleting the older tiled-time windows toward the tail end if a delete condition is satisfied. This delete condition is used in conjunction with the Apriori property to further limit the level of consumption in main memory.

The strength of this algorithm is its ability to answer queries about the frequent patterns between any two time instances. The answers to the queries are much more precise at the expense of a much higher processing cost and memory cost. As a result, it is difficult to consider FP-Streaming an online algorithm where real-time responses are required from high speed data streams. Nevertheless, this work forms the basis for mining patterns under time-changing conditions. Subsequent works addressed the various aspects of this issue include the use of sliding windows in Chang^[47] and Chang^[48] for better real-time analysis; finding the difference in patterns of two data streams;^[49] and finding temporal patterns.^[50]

Clustering

Clustering is the process of partitioning a group of records into subgroups (or clusters) such that the data points in each group are similar to the other points in the same group but are different to the data points in the other groups.^[51] Clustering algorithms predominantly fall into two main techniques. The *partitioning* method, where k partitions are predefined and the objects are then placed, based on greedy heuristics, into a partition based on some objective function. The other approach is the *hierarchical* method, where the algorithm works either in a top-down or bottom-up approach. In the top-down approach, all data objects are initially in one cluster and in each iteration, the algorithm divides the clusters into smaller clusters. In the bottom-up approach, each data object started as a cluster and up iteratively merged until the desired number of clusters is reached.

The nature of data streams presents three key challenges clustering algorithms: 1) the compactness of the representation; 2) incremental process of new data objects; and 3) clear identification of outliers. The first challenge meant that the clusters must be representable in a form that is independent on the size of the growing data stream. The second challenge meant that clustering algorithms must be capable of placing a newly arrived data object quickly into a cluster. In other words, the similarity function must depend on the comparison of all data objects. Finally, the last challenge is the need to quickly identify outliers. This is more difficult than it appears to be due to the fact that an outlier at some point in time may form a new cluster in the

future. In the sections that follow, we review some of the algorithms for clustering data streams.

CluStream and variants

Probably the most representative algorithm for clustering data streams is CluStream first reported in Aggarwal.^[52] CluStream was designed to address the issue of discovery over evolving data streams. To address this problem, two novel concepts were proposed: 1) the use of microclusters which is an extension of the feature vector in BIRCH;^[53] and 2) the pyramidal timeframe.

Essentially, the microcluster is some sort of summary structure for the atomic cluster obtained from the online component of CluStream. It maintains statistical information about the data points assigned to the cluster which is used to compute the centroid. A micro-cluster is defined as a $(2d + 3)$ tuple $(\overline{CF2^x}, \overline{CF1^x}, CF2^t, CF1^t, n)$, where d is the dimension of data points. $\overline{CF2^x}$ and $\overline{CF1^x}$ are the sum and squared sum of the data values for each dimension in the cluster respectively and both are vectors of d entries. Correspondingly, $CF2^t$ and $CF1^t$ are the sum and squared sum of the time stamps; and n is the number of data points assigned in the cluster.

The pyramidal timeframe is a table that stores snapshots (at different time instances) of the microclusters. Periodically, a snapshot is taken to capture the set of microclusters in existence. As the snapshot becomes “older” overtime, less space is allocated to store information about the microcluster at that time instance. That is, the longer the snapshot of the microclusters exist in the pyramidal timeframe, the more space is allocated and hence, the microclusters are further summarized by merging the information that two microclusters contain. The algorithm in CluStream that uses the above concepts is given below.

1. Initially, CluStream clusters off-line from an initial set of data points to create the initial q -clusters.
2. After that, the online component kicks in. When a new data point arrives, it will be clustered into one of q clusters and the corresponding microcluster updated. The new data point may end up as a new cluster to reflect the evolution in the data stream. In order to get more space for new clusters, the old ones may be deleted if they are identified as outliers, or two old clusters may be merged.
3. Periodically, a snapshot is taken to capture the set of q microclusters, and that is stored in the pyramidal timeframe. The old snapshot is deleted (if the pyramidal timeframe is full), or the latest snapshot is “aged” to the next slot before inserting the new snapshot in the latest slot.
4. The off-line component is used each time a query is made. The answer to the query will come from the

summary information held in the pyramidal time-frame and the q clusters.

The design in CluStream allows the algorithm to store the status of the data stream at different time instances and thus allow interesting queries to be issued. For example, given two different time instances, we can compare the differences in the clusters formed to understand how a particular cluster has evolved and potentially identify the data item(s) that caused the change.

The CluStream framework was later utilized in Ong^[54] to cluster categorical data streams. Named SCLOPE, the algorithm was derived from three previous works namely, CLOPE,^[55] CluStream, and FP-tree.^[46] In SCLOPE, a categorical data stream is divided into windows. With each window, the online component is utilized to construct a FP-Tree for all transactions appearing in the window similar to the algorithm proposed in Han^[46] but with additional information about each branch of the data structure. From the constructed FP-Tree, SCLOPE groups the similar paths, i.e., those branches sharing the same prefix in the FP-Tree into microclusters. Since each branch represents a set of similar transactions and that overlapping branches are more similar than those that do not, the effect is similar to clustering as observed in CLOPE. Once the local microclusters are created, the off-line component is applied to cluster them into global clusters using the CLOPE algorithm.

Another variant of the CluStream algorithm is the StreamCluCD algorithm. This algorithm is designed based on the Lossy Counting algorithm discussed in Manku.^[29] In this algorithm, each cluster is represented by a histogram (for all m attributes), which are used to compare the similarity of a new record to the cluster. When a new data object arrives, it is compared with the histogram to determine the best cluster for the data object. The cluster's histogram is then updated to reflect the new data object. If no cluster fits, the data object becomes a new cluster if the space constraint, controlled via the ϵ and s parameter in the Lossy Counting algorithm, is not violated. The drawback of this algorithm is in the sensitivity of the objects chosen as the initial clusters.

k -Median

An alternative approach to CluStream is based on approximation algorithms to cluster the data points in metric space.^[32,56–59] k -Median is one such notable algorithm, where the sum of the distance from each data point to its closest assigned median is expected to be minimized.

Let $\omega = (N, dist)$ be a metric space, where n is a ground set and $dist : N \times N \rightarrow \mathbb{R}^+ \cup \{0\}$ be a distance function. Further, let M be a median set and Y be the data set that we want to cluster into k clusters, where both are the subsets of N . Then for all data points $x \in Y$, we

denote $ASG(x, M) = \min_{m \in M} dist(x, m)$ as the closest member of M to x , and denote $AD(x, M) = dist(x, ASG(x, M))$ as the assignment distance of x under the set M . Using these notations, the cost function of k -median problem can be defined as

$$\phi^Y(M) = \sum_{x \in Y} AD(x, M) \quad (1)$$

Thus, the objective of k -median is to find a set M that can minimize the cost function $\phi^Y(M)$. The k -median problem can be further divided into two subproblems: continuous k -median and discrete k -median. We call continuous k -median if the set M is chosen from space N , which means it is not limited in Y . Otherwise, we call discrete k -median, i.e., M is chosen from Y .

To cluster stream data, bicriterion (a, b) approximation algorithms are often used. In this approach, the produced set M has at most $a \times k$ medians and the cost function for that M is no more than b times the cost of the optimal solution. An algorithm for k -median problems was introduced in Guha^[32] and Guha,^[56] where the algorithm builds clusters (using the bicriterion) incrementally and hierarchically. Like SCLOPE, the algorithm processes the stream in batches of data points, each fitting the primary memory. The algorithm is summarized below.

Let m be the size of memory, k be the given number of expected clusters. This algorithm can be summarized as follows:

1. Let m be the number of data points that can be held in primary memory. Upon receiving m data points, the algorithm clusters them into $2k$ points, i.e., $a = 2$. These points are called *intermediate medians* and are weighted by the number of data points assigned to it.
2. The algorithm reiterates the step above until it has $m^2/2k$ data points from the data stream, where it will cluster the m first-level medians into $2k$ second-level medians. Each median in the $2k$ new intermediate medians is also weighted by the total number of data points assigned to it.
3. Maintaining at most mi -level medians and on seeing m data points, the algorithm generates $2k(i + 1)^{\text{th}}$ -level medians with the weight of each new median as the sum of the weights of all intermediate medians assigned to it.
4. When users request the result, the algorithm clusters all intermediate medians into k final medians.

This approach was later improved by Charikar^[58] and Mishra,^[59] where the accuracy of the approximation factor b is enhance and the memory is better utilized. Babcock et al.^[57,60] later extend the solution to work in a window model rather than processing them in batches. The advantage of these algorithms is that they can process the data stream in limited space, and the clusters are represented in

a compact manner—it only requires the set of medians to be recorded. On the down side, these algorithms are extensions of the k -median and thus find hyper-spheres as clusters. Additionally, it is not clear how these approaches can be extended to categorical data streams.

Classification

In contrast to clustering, the objective of classification is to build a model that can be used to predict the class (or missing attribute value) of a future data object whose class (or the value of interest) is unknown. Generally, classification is a two-step process.

In the first step, as known as learning, the model is built from a set of training samples, where the class of each sample is known in advance. In the second step, the model constructed by the algorithm by learning from the samples are used to predict future objects.^[61] Typically, the learning models are represented as classification rules, decision trees, or some mathematical function. Classification using decision trees has been well-studied and many algorithms were developed.^[62] Classification using the Bayesian^[63] network is a technique based on statistics. There are also techniques in machine learning and neural networks.^[61,64–66] In the sections that follow, we review the data stream variants that were built on the foundations of these classic algorithms.

Very fast decision tree (VFDT) construction

VFDT^[67] builds a decision tree for classification based on the Hoeffding bound. The initial state of the decision tree consists of only one single leaf node, i.e., the root node. As data points arrive, the tree is built iteratively (starting from the root) by replacing the leaf nodes with decision (or test) nodes. To do this, statistics about the data points are stored at each leaf node. The statistics include the counts n_{ijk} representing the number of data points of class label k reaching that leaf node when the attribute j receives the value i .

The decision on whether a node is to become a test node depends on two factors—whether there are enough data points at the leaf node, and whether the selected heuristic evaluation function, e.g., C4.5 or the Gini index, supports the split. If both criteria are met, the node is changed into a decision node and one of the available attributes is selected as the test condition. This is done throughout the lifetime in processing the data stream. The significant strength of VFDT is the time cost to evaluate the heuristic evaluation function each time a data point arrives at a leaf node. VFDT minimizes this cost by evaluating the function using only those data points since the last evaluation. This is further capped by using the minimal number of such points using the Hoeffding bound before deciding to split a leaf node.

One weakness of VFDT is that it assumes the underlying stream to have a stationary distribution.^[67] And if the

datapoints are buffered on disk, performance takes a hit as the data points are read at random.

VFDT for continuous attributes

An extension of VFDT is reported in Gama^[68] for continuous attributes. Named VFDTc, a decision node has only two descendent branches and the splitting test is a condition of the form $\text{attribute}_i \leq \text{cuttingpoint}$. Therefore, the two descendant branches correspond to the values of *true* and *false* as returned by an evaluation of the condition.

To identify the cutting point, a vector representing the distribution for the data points reaching a leaf node is maintained, and for each continuous attribute, a binary tree is maintained. Each node in the binary tree contains three fields. The first is the node identifier, which is also the value i of the attribute. The other two are vectors of k dimensions, where k corresponds to the number of classes. Each time a data point reaches the leaf, all its binary trees are updated. From these binary trees, the information gain of a given attribute can be computed. Hence, the best attribute with its best cutting point can be found.

On the drawback of this algorithm, this approach is computationally expensive due to the amount of work needed to create metadata for identifying the split. Also, VFDT does not work well on data streams where concept drifts occur.

Concept-adapting VFDT

Where concept drifts occur in the data streams, the decision tree constructed by VFDT quickly becomes outdated and so, the prediction accuracy on new data objects drops significantly over time. To address this problem, Hulten et al.^[69] proposed an extension of the VFDT. Called concept-adapting VFDT (or CVFDT), the decision is built from at most n data points. And unlike VFDT where only leaf nodes are required to store sufficient statistics, the decision nodes in CVFDT must also maintain sufficient statistics.

To maintain concept drifts, the CVFDT algorithm periodically scans the decision nodes and for those nodes whose sufficient statistics suggest some new attribute that would be a better candidate for the test condition, an alternative subtree starting at that node is created. Over time, as the new subtree becomes more accurate than the older one, the old subtree is replaced. Hence, there can be more than one subtree rooted from the same internal node in CVFDT. In this case, there are instances when CVFDT actually maintains them simultaneously.

Ensemble classifiers

The classifiers that we have discussed thus far built a single model to predict every possible outcomes in the data stream. The issue with this approach is the implicit

assumption that the training data and the testing data shared a similar distribution. While this assumption is arguably reasonable, it contradicted with the assertion that a data stream's distribution and its characteristics do evolve over time. Consequently, it was argued in Wang,^[70] Fan^[71,72] and Gao^[73] that a better model is to have a number of classifiers working on the same data stream where the results among the classifiers are combined to give a prediction. This led to the development of a generic framework to discover concept drifting data streams using weighted ensemble classifiers.

In Wang et al.'s^[70] framework, the set of classifiers may be a combination of models, e.g., decision trees, Naive networks, Ripper, etc., learnt using different techniques or algorithms. The ensemble of classifiers will build the top k -classifiers that can learn with the best accuracy. To do so, the data stream is processed in "chunks." When a chunk of data points arrives, a new classifier is created for that chunk. At the same time, the same chunk is used to update the weights of the older classifiers. The weight of each classifier is updated based on the expected error of that classifier in predicting the data points in the new chunk. Often, this weight is inversely proportional to the error value. The top k -classifiers that gave the most accurate prediction are chosen into the ensemble.

This approach has the advantage that it can produce a better prediction than the single classifier approach.^[67] The disadvantage lies in the complexity of maintaining the set of k classifiers. Furthermore, the results are often sensitive to the size of the data chunk and the number of classifiers in the ensemble. Given that different types of classifiers are picked in the ensemble, trying to identify the proper parameter is often not easy—especially when the data stream is concept drifting.

StreamMiner

StreamMiner^[71,72,74] is a classifier system that can detect and learn changing in data streams automatically. The system relies on the decision tree model. There are two types of changes that StreamMiner can learn: concept drift and distribution drift.

Different from other learning systems, StreamMiner does not need the labeled data in new data stream immediately. It only needs when the change is detected. To identify the change, it bases on statistically estimated loss measures. In detail, firstly, the model based on the decision tree is built from a training data set. When processing new stream data, the system compares the statistical value at each leaf in the tree to detect the change. Let dt be a decision tree constructing from training data set D ; and S be a data stream. Each instance in S is classified by a unique path from the root to some leaf node. Assume that n is the number of instances classified by leaf ℓ ; and N is

the size of the data stream seen so far. The statistics at leaf ℓ is defined as

$$P(\ell) = \frac{n_\ell}{N} \quad (2)$$

Clearly, the sum of $P(\ell)$ overall leaf nodes in the tree dt is equal to 1, i.e., $\sum P(\ell) = 1$. The $P(\ell)$ describes how the instance space of the stream S is shattered among the leaf nodes solely based on attribute test results of the given decision tree dt . It does not consider either the true class labels or attributes that are not tested by dt . Now the statistical difference between the training data set D and the stream data S can be identified. This value will be reflected in $P(\ell)$ as follows

$$PS = \frac{\sum_{\ell \in dt} |P_S(\ell) - P_D(\ell)|}{2} \times 100 \quad (3)$$

where

$PD(\ell)$ is statistics at leaf ℓ on the training data set D

$PS(\ell)$ is statistics at leaf ℓ on the data stream S .

This PS is called the *error rate* or *guessed loss* of the model on the new stream data. Therefore, this approach does not need the labeled data in the data stream for identifying the change. Instead, it compares statistical difference at each leaf node in the model. If this PS value is much higher than an application-specific tolerable maximum value, a small number of data records in the new data stream is chosen to investigate their true class labels. This means, only after "guessing" there are some changes in the data stream that the model may not be suitable, the system needs to identify true labels of some samples in the new streaming data. With these true class labels, the true loss of current decision tree is statistically estimated. If this value is also higher than the tolerable maximum value, the decision tree should be reconstructed by using the same true class labels sampled in the previous step. This system has been tested and used for credit card fraud detection applications.

CONCLUSIONS

It might appear to some readers that data stream problems are very much restricted to a few application domain and thus, the solutions may not deliver an impact on a larger scale. For example, it is probably easier to see the value of a clustering algorithm on any data applications over a clustering algorithm in the data stream environment that is restricted to only a few specific applications. In our opinion, this view does not do justice to the solutions brought about by data stream problems.

Regardless of the application, we are witnessing an exponential growth in the amount of data to be processed. And that has kept the data mining and database

community working on better algorithms to process the larger volume of data. If we consider the bigger picture of data analytics, the larger data set affects not just analytical times but also the ease at which the analytics can be presented and interpreted by the analyst. Since it has been known that data mining is an iterative and interactive process, the analyst will require multiple runs of the algorithm with different parameters. Consequently, the exact results may not be paramount during analysis, and improvements in the level of interactivity between the algorithm and the analyst is often preferred.

In other words, the analysis of data usually begins with the analyst forming a hypothesis and so, the algorithms are run with parameters to obtain analytics that verifies that hypothesis. In most cases, this process would involve fine tuning of the algorithm's parameters as the analyst tries to zero in on the results. Therefore, the intermediate results during the process serve more to give directions to the analyst rather than giving the answer to the hypothesis. If so, the analysis would be more productive if the analyst's chain of thoughts are not broken, and that the analyst does not have to wait for the algorithm.

This is where the techniques brought about by data stream problems can be useful. Since data stream algorithms process data far more quickly than conventional algorithms and give an estimate in real time, the level of interactivity is much higher between the algorithm and the analyst within the same time period. Therefore, we argue that the analyst is likely to zoom in on the right results far more quickly than using conventional algorithms.

It is on this basis that we believe data streams algorithms might be the way future data mining algorithms are developed. The amount of data will continue to grow larger although they might not necessarily become data streams. However, when the data set is sufficiently large, the benefits of data stream techniques will no doubt become useful.

Knowledge Management

Kimiz Dalkir

Graduate School of Library and Information Studies, McGill University, Montreal, Quebec, Canada

Abstract

Knowledge management (KM) is defined as a deliberate and systematic coordination of an organization's people, technology, processes, and organizational structure in order to add value through reuse and innovation. There is a lack of consensus on clearly defining KM partly due to the multidisciplinary origins of the concept, ranging from organizational science, to cognitive science, to library and information science. Core management concepts include the notion of difficult to articulate tacit knowledge, documented tangible or explicit knowledge, organizational learning as encapsulated in the form of best practices (successes) and lessons learned (failures), and preservation of this content in an organizational memory system. The knowledge processing life cycle then consists of creating new knowledge; capturing existing knowledge; contributing knowledge for reuse by others; documenting knowledge; reconstructing, refining, and sharing knowledge; and continually evaluating the value of each knowledge resource in order to decide whether to keep it in circulation or to retire it from "active duty." The Nonaka and Takeuchi knowledge spiral model is used to illustrate how knowledge is transformed from one form to the other. A brief historical overview of KM is presented to show the evolution from a management fad to a scholarly discipline of study and research. Finally, the emerging roles for information professionals in this field are briefly described, outlining some of the key roles such as chief knowledge officer, knowledge manager, content editor, and knowledge journalist.

INTRODUCTION

This chapter provides an overview of knowledge management (KM), both as a scholarly discipline and a professional field of practice. Key terms such as "knowledge" and "knowledge management" are defined. Core concepts such as intellectual capital, lessons learned, best practices, and value-added knowledge reuse are introduced and defined. Key stages in the knowledge processing cycle are defined and described. A brief historical chronology of KM is outlined to show the multidisciplinary roots and the evolution that has taken place to date. The emerging roles for information professionals in KM are presented, and the links to information studies are emphasized. The primary goal of this chapter is to illustrate how KM that rests on a solid foundation of information management emerges as a stronger and more rigorous field of study and practice.

DEFINITION OF KNOWLEDGE MANAGEMENT

There is no universally accepted definition of KM. Part of this stems from the fact that there is a lack of consensus in defining knowledge. A sample dictionary definition of knowledge is

"the fact or condition of knowing something with familiarity gained through experience or association; acquaintance with or understanding of a science, art, or

technique; the fact or condition of being aware of something; the range of one's information or understanding (e.g., answered to the best of my *knowledge*); the circumstance or condition of apprehending truth or fact through reasoning; the sum of what is known: the body of truth, information, and principles acquired by humankind; cognizance, awareness, learning."^[1]

It is useful to view the knowledge in KM as being composed primarily of experiential knowledge that is highly subjective in nature. This can be contrasted with information which, although subject to different interpretations, is typically thought of as having a more neutral and verifiable nature. The same dictionary defines information as

"knowledge obtained from investigation, study, or instruction; intelligence, news data or facts; the attribute inherent in and communicated by one of two or more alternative sequences or arrangements of something (as nucleotides in DNA or binary digits in a computer program) that produce specific effects c 1: a signal or character (as in a communication system or computer) representing data 2: something (as a message, experimental data, or a picture) which justifies change in a construct (as a plan or theory) that represents physical or mental experience or another construct."^[1]

Other definitions from the KM literature include the following:

"Knowledge is a subset of information: it is subjective; it is linked to meaningful behaviour; and it has tacit

Fig. 1 Key attributes of knowledge assets.

elements born of experience”(Leonard and Sensiper,^[2] p. 113).

Knowledge is always recreated in the present moment. Most of us cannot articulate what we know. It is largely invisible, and often comes to mind when we need it to answer a question or solve a problem.^[3]

“Knowledge is a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices and norms” (Davenport and Prusak,^[4] p. 5).

A typical example of information would be to read the listings of movies being shown on a given week, reading the reviews, and consulting the times and places the film will be showing at. An example of knowledge would be calling on a friend who has, in the past, demonstrated an uncanny inverse relationship with respect to likes and dislikes: if this person liked a movie, experience has shown that I would hate it and vice versa. Knowledge is also brought into play in making a decision to drive or take public transport, given the time of year, possibility of inclement weather, and the rapid trend analysis that concludes that it was never possible to find parking in time to see a movie being shown downtown.

A key point is that not all information is of value to a given individual, group, or organization. A knowledge asset is defined as knowledge that is of value, which is more context dependent and more subjective in nature, as illustrated in Fig. 1.

The Multidisciplinary Nature of Knowledge Management

There is a great diversity to be found in KM definitions. This is due to the multidisciplinary nature of the field. In fact,

Table 1 Diverse disciplines that contribute to knowledge management

1.	Organizational development, organizational science, organizational learning
2.	Cognitive science, individual learning, mental models
3.	Linguistics and computational linguistics
4.	Information technologies such as knowledge-based systems, document and information management, electronic performance support systems, and database technologies
5.	Information and library science, classification, taxonomy
6.	Technical writing and journalism
7.	Anthropology and sociology, sociograms, social network analysis
8.	Education and training
9.	Storytelling and communication studies
10.	Collaborative technologies such as CSCW and groupware, as well as intranets, extranets, portals, and other web technologies

most definitions appear to provide only one piece of the KM definition puzzle, as they are heavily influenced by their particular discipline. Table 1 lists some of the different disciplines that have contributed to and that make use of KM.

Here are a few sample definitions from the business perspective:

Knowledge management is a business activity with two primary aspects: treating the knowledge component of business activities as an explicit concern of business reflected in strategy, policy, and practice at all levels of the organization and making a direct connection between an organization’s intellectual assets—both explicit (recorded) and tacit (personal know-how)—and positive business results.^[5]

Knowledge management is a collaborative and integrated approach to the creation, capture, organization, access, and use of an enterprise’s intellectual assets.^[6]

“There is much more to knowledge management than technology alone. Management is a business process” (Sarvary,^[7] p.95).

Some definitions from the cognitive science or knowledge science perspective are as follows:

Knowledge—the insights, understandings, and practical know-how that we all possess—is the fundamental resource that allows us to function intelligently. Over time, considerable knowledge is also transformed to other manifestations—such as books, technology, practices, and traditions—within organizations of all kinds and in society in general. These transformations result in cumulated (sic) expertise and, when used appropriately, increased effectiveness. Knowledge is one, if not *the*, principal factor that makes personal, organizational, and societal intelligent behavior possible.^[8]

Some sample definitions from the process/technology perspective are the following:

Knowledge management (KM) was initially defined as the process of applying a systematic approach to the capture, structuring, management, and dissemination of knowledge throughout an organization to work faster, reuse best practices, and reduce costly rework from project to project.^[9–11]

APQC^[12] defines KM as systematic approaches to help information and knowledge emerge and flow to the right people at the right time to create value.

Some “people-oriented” definitions are as follows:

“Knowledge management is not seen as a matter of building up a large electronic library, but by connecting people so they can think together” (McDermott,^[13] p.104).

“Most executives seem to understand that knowledge is highly people-based, but they are stuck with an investment model that is geared primarily toward technology implementations” (Ruggles and Holtshouse,^[14] p. 86).

Wiig^[13] also emphasizes that given the importance of knowledge in virtually all areas of daily and commercial life, two knowledge-related aspects are vital for viability and success at any level. These are knowledge *assets* that must be applied, nurtured, preserved, and used to the largest extent possible by both individuals and organizations and knowledge-related *processes* to create, build, compile, organize, transform, transfer, pool, apply, and safeguard knowledge—must be carefully and explicitly managed in all affected areas.

“Historically, knowledge has always been managed, at least implicitly. However, effective and active knowledge management requires new perspectives and techniques and touches on almost all facets of an organization. We need to develop a new discipline and prepare a cadre of knowledge professionals with a blend of expertise that we have not previously seen. This is our challenge!” (Wiig^[8]).

The Intellectual Capital Perspective

The focus of Intellectual Capital Management (ICM), on the other hand, is on those pieces of knowledge that are of *business value* to the organization—referred to as intellectual capital or assets.^[15] While some of these are more visible (e.g., patents, intellectual property), the majority consists of know-how, know-why, experience, and expertise that tend to reside within the head of one or a few employees.^[16,17]

KM is often characterized by “pack rat” approach to content: “save it, it may prove useful some time in the future.” Many documents tend to be warehoused, sophisticated search engines are then used to try to retrieve some of this content, and fairly large-scale and costly KM systems are built. KM solutions have proven to be most successful in the capture, storage, and subsequent dissemination of knowledge that has been rendered explicit—particularly lessons learned and best practices.

ICM is characterized by less content—because content is filtered and judged and only the best are inventoried (e.g., the “top ten”). ICM content tends to be more representative of peoples’ real thinking (contextual information, opinions, stories) due to its focus on actionable knowledge and know-how, resulting in less costly endeavors and a focus on learning (at the individual, community, and organizational level), rather than on the building of systems.

It is essential to identify that knowledge is of value and is also at risk of being lost to the organization, through retirement, turnover, and competition. The best way to retain valuable knowledge is to identify intellectual assets and then ensure legacy materials are produced, and subsequently stored in such a way as to make their future retrieval and reuse as easy as possible.^[18] These tangible by-products need to flow from individual to individual, between communities of practice (CoPs) members, and, of course, back to the organization itself, in the form of lessons learned, best practices, and corporate memory.

The knowledge capture and transfer approaches described here thus help to

- Facilitate a smooth transition from those retiring to their successors who are recruited to fill their positions
- Minimize loss of corporate memory due to attrition and retirement
- Identify critical resources and critical areas of knowledge so that the corporation “knows what it knows and does well—and why”
- Build up a toolkit of methods that can be used with individuals, with groups, and with the organization to stem the potential loss of intellectual capital

Knowledge management is often mistakenly perceived as a process of documenting knowledge held in people’s minds, then storing or archiving this knowledge.^[19] In fact, it is better to view KM in a broader context, one that encompasses all the processes used to generate value from knowledge-based assets. Knowledge management is facilitated by technology and by the culture of an organization. A good way of defining KM is

...the deliberate and systematic coordination of an organization’s people, technology, processes and organizational structure in order to add value through reuse and innovation. This is achieved through the promotion of creating, sharing and applying knowledge as well as through the feeding of valuable lessons learned and best practices into corporate memory in order to foster continued organizational learning. (Dalkir,^[20] p. 3)

CORE KNOWLEDGE MANAGEMENT CONCEPTS

Kransdorff^[21] coined the term “corporate amnesia” to refer to the loss of accumulated expertise and know-how

due to employee turnover as people take what they know with them when they leave. The costs of employee turnover to the organization have been well documented (e.g., separation costs, recruitment and selection costs, training of replacements, initial lack of productivity of new hire, and the loss of productivity of co-workers during the transition). Far less research attention has been paid to the cost to the firm of losing know-how that resides within the minds of individual employees who depart. In an era of knowledge workers, learning organizations and service economies individuals are increasingly responsible for value creation. Although many organizations have succession plans in place, the process usually involves transferring know-how from the departing employee to their successor, but the whole process has to be repeated again for the next departure. Organizations need to “capture” this know-how and transfer it to a stable, easily accessible, cumulative knowledge base—an organizational memory—to retain and make accessible valuable knowledge gained through the experiences of all knowledge in a continuous and uninterrupted manner.

Organizations need to effectively manage their organizational memory in order to prevent the loss of essential knowledge, particularly knowledge that resides predominantly in the heads of their knowledge workers (“tacit knowledge”) and less in documents, procedures, and other tangible forms (“explicit knowledge”).^[22] More often than not, it is this difficult to articulate “know-how” that is of greatest value in organizational competitiveness and viability and which represents the vast majority of experiential know-how. Fig. 2 shows how the metaphor of an

Fig. 2 The iceberg metaphor used to show the respective proportions of tacit and explicit knowledge.

iceberg is often used to depict tacit and explicit knowledge forms.

The National Aeronautics and Space Administration (NASA), for example, has publicly admitted that the knowledge of how to put a man on the moon has been lost.^[23] The lessons that were learned and the innovations that were sparked cannot be found in the collective organizational memory of NASA. This means that NASA’s organizational memory cannot be used as a resource to plan a more effective mission to send another manned flight to the moon or to Mars. A well-designed and well-managed organizational memory does not only combat corporate amnesia, but it ensures knowledge continuity—the effective transfer of know-how among peers and to future generations of knowledge workers. A better understanding of the nature of organizational memory, what it should include (content), how it can best be retained (technological containers), and how the accumulated lessons learned and best practices can be used by newcomers (connections) will help mitigate the cost of lost, forgotten, or untransferred knowledge and know-how.

Organizations today face escalating risks of losing strategic knowledge and know-how and face incredible difficulties in recruiting and retaining skilled employees. Many industries face astounding rates of high and constant turnover. In addition, we are experiencing a demographic pressure as baby boomers are rapidly approaching the retirement age, which means that a “critical mass” of knowledge will literally walk out the door over the next 5–10 yrs. Approximately, 11,000 baby boomers are turning 50 yrs old every day.^[24] In the Canadian federal government, for example, 15,000 civil servants are expected to retire within the next 5 yrs.^[25] In the United States, more than 50% of the government workforce will be eligible for retirement by 2004.^[28] Other vulnerable include organizations high technology companies with very high turnover rates and the military or banking, where constant turnover is the norm given rotational postings. Since 2007, “...the total, the number of people not in the labor force rose by 12.6 million (16%) from the fourth quarter of 2007 to the fourth quarter of 2013.”^[27] The aging of the workforce is a trend that does not show any signs of slowing down: “America is getting older, a trend that will undoubtedly continue to have a profound impact on the labor market going forward.”^[28]

The most successful organizations will state that their two greatest assets are the people who work for them and the knowledge they possess. The imminent turnover signals a potential for the loss of valuable accumulated knowledge and know-how in the form of the competence and expertise possessed by the departing individuals. This valuable knowledge and know-how exists in both formal and tangible forms, such as documents, but also in less visible forms—often referred to as tacit or difficult to articulate knowledge. Particular emphasis must be placed on the tacit form as this often resides within a given individual or group and is therefore more

easily and completely lost when the people leave the organization.^[29]

The typical technological tools used in KM are some form of centralized database system, an intranet or web portal to access the database content, as well as other organizational knowledge, some type of messaging system (typically e-mail and discussion groups), some content management tools to organize the knowledge resources (e.g., content management software, taxonomy software), and some form of collaborative software (e.g., virtual meeting tools, groupware).

The essential elements that go into organizational memory include best practices, which are innovations or improved practices, processes and so forth; together with the flip side of the coin: lesson learned, outcomes that were not desirable, or errors that should not be repeated. By carefully capturing, documenting, organizing, and making available accumulated experiential knowledge in the form of best practices and lessons learned, KM can provide a framework within which we can process knowledge throughout its useful life cycle.

Knowledge management typically addresses three levels within an organization: the individual, the group, and the organization. Organizational memory resides at the level of the organization, and this is the preservation layer of KM. Innovation and knowledge creation occurs at the individual level, while knowledge dissemination and sharing occur at the group level. In KM, groups of a particular nature, called “communities of practice”, are often a key element in ensuring that valuable knowledge flows or moves around appropriately. These CoPs are essentially thematic networks of like-minded individuals who share a common purpose, a common professional zeal, and agree to mutually help out one another to achieve some strategic goals for the organization.^[30,31]

Szulanski^[32] introduced the notion of knowledge “stickiness” to refer to knowledge that was difficult to move around and thus could provide little in the way of value to individuals, groups, or the organization as a whole. The knowledge processing cycle is used to describe the various stages a particular knowledge resource goes through during the course of its “life span” within an organization.

THE KNOWLEDGE PROCESSING CYCLE

Nonaka and Takeuchi described how knowledge was disseminated and transformed as it made its way around an organization in their knowledge spiral model.^[9] Essentially, knowledge is created by an individual, who has an innovative idea, for example, but remains initially tacit. This innovation or idea is typically shared only with trusted friends and colleagues at first (“socialization”). With time, others may be aware of the innovation, and the knowledge may be transformed from its tacit state to

Fig. 3 The Nonaka and Takeuchi knowledge spiral model of KM.

an explicit one (“externalization”), by documenting it in the form of text, audio, or other formats. Once explicit, it is easier to disseminate more widely and to preserve in an organizational memory system. At this stage (“combination”), the content may be better organized and reworked (e.g., addition of an abstract or executive summary). In the final stage (“internalization”), explicit knowledge once again becomes tacit as an individual learns, understands, and “buys into” a knowledge resource (e.g., sees its value and decides to apply this new knowledge). The knowledge resource then continues cycling through the four quadrants in a “knowledge spiral.” Fig. 3 outlines the major stages in the Nonaka and Takeuchi KM model, as knowledge is transformed, disseminated, and applied within an organization.

As knowledge resources circulate throughout an organization, value can be added at each step. A more detailed view of what happens to knowledge as it undergoes transformation from tacit to explicit and back again is provided in the form of a knowledge life cycle. The first stage is to either capture existing knowledge (e.g., already existing in tangible form such as project reports, conference reports, or other documents) or to create knowledge that does not yet exist in documented form (e.g., by interviewing subject matter experts to document a particular procedure). This knowledge resource can then be contributed or made available for reuse by others. Knowledge is then codified by the addition of sufficient descriptive information about both the content and the format it is in (e.g., metadata describing theme, whether it is a text or also available as a short video clip). At this point, knowledge is further refined by sanitizing (removing all sensitive information that may identify a person, place, or event or other confidential content) and reconstruction (e.g., recombining or synthesizing in a new version). Contributions that have been refined and reconstructed are then subjected to a selective filtering process, and those that are deemed to be valuable are made available for knowledge sharing.

Table 2 Key steps in a knowledge processing cycle

Step number	Description
1.	Knowledge capture
2.	Knowledge creation
3.	Knowledge contribution
4.	Knowledge codification
5.	Knowledge refinement (including sanitize) and reconstruction (e.g., synthesis)
6.	Knowledge selection—filter contributions
7.	Knowledge sharing and pooling
8.	Knowledge organization and access
9.	Knowledge learning and application
10.	Knowledge evaluation and reuse or divest (e.g., destroy, archive)

Knowledge sharing involves the pooling and distribution of valuable content, either globally (e.g., a “broadcast” mode) or selectively (e.g., targeted to specific users, communities, or based on user profiles, and subscriptions). The knowledge is better organized (classified using a taxonomic scheme), and access is typically provided through an intranet or portal interface. These valuable knowledge resources are then learned and applied by knowledge workers. Each knowledge resource is evaluated periodically in order to ensure continued relevance and to decide whether to discard or to archive at the appropriate time. Table 2 lists the key phases in knowledge processing that occurs during the useful life cycle of a knowledge resource, such as a best practice or lesson learned.

A more recent review of existing KM life cycle models^[33] compared and contrasted the different approaches. A number of different terms were found to be used for essentially the similar types of knowledge processing activities. The result of this analysis led to the formulation of a holistic KM life cycle model with seven core steps: *identify, store, share, use, learn, improve, and create*. One of the major advantages of this framework is that it builds upon existing frameworks and adds in the notion of double loop learning in order to capture the nonsequential or cyclical nature of knowledge processing. The key KM objectives of reuse for efficiency are also complemented by the goals of learning to continually improve, at the individual, group, and organizational levels.

HISTORY AND EVOLUTION OF KNOWLEDGE MANAGEMENT

Knowledge and management are concepts that have obviously been around for some—the combination, “knowledge management,” however, is fairly recent. The emergence of communication technologies that create real-time networks such as the Internet, intranets, e-mail, and so forth has made KM easier to implement.^[34]

A number of management theories have contributed to the definition of KM. Two KM gurus were responsible for establishing the field as a serious target for scholarly study: Peter Drucker,^[35] who coined the term “knowledge worker” and who wrote about KM from a management perspective in the 1970s, and Nonaka and Takeuchi, who wrote the seminal book *The Knowledge Creating Company* in the 1990s.^[9] Others such as Peter Senge^[36] and Chris Argyris^[37,38] have focused on the “learning organization” and cultural dimensions of managing knowledge. By the mid-1980s, the notion of knowledge as an asset became more widely adopted. Early pioneers in information technologies from artificial intelligence and expert systems at Carnegie Mellon University (CMU) and Digital Equipment Corporation (DEC) developed hypertext and groupware tools that allow information to be better shared and organized. Knowledge management-related articles began appearing in prestigious journals such as the *Harvard Business Review* and *Organization Science*, and a number of foundational books were published such as *The Fifth Discipline* and *The Knowledge-Creating Company*. Table 3 illustrates the major milestones in KM history.

In 1989, the International Knowledge Management Network (IKMN) was founded in Europe and was joined by the U.S.-based Knowledge Management Forum in 1994. Businesses began implementing KM solutions in earnest in the 1990s. At first, projects tended to be technological implementations, mostly portals and knowledge repositories. This was followed by a wave of “people-not-technology” emphasis that led to the popularity of thematic networks or CoPs. A third wave emerged as knowledge workers, much like information workers, found themselves faced with “content overload” that in turn led to a number of content management, knowledge organization, or taxonomic classification projects to make the knowledge more readily accessible to users.

Table 3 Major milestones in KM history

Year	Source	Event
1980	DEC, CMU	XCON Expert System
1986	Dr. K Wiig	Coined KM concept at UN
1989	Consulting firms	Start internal KM projects
1991	HBR article	Nonaka and Takeuchi
1993	Dr. K Wiig	First KM book published
1994	KM Network	First KM conference
Mid-1990s	Consulting firms	Start offering KM services
Late 1990s	Key vertical industries	Implement KM and start seeing benefits
2000–2003	Academia	KM courses/programs in universities with KM texts
2004–present	Professionalization of KM	Professional certification in KM, master’s and PhD degrees in KM conferred by universities, and KM job titles in a broad range of sectors

With the new millennium, KM faded a bit from public view, likely due to disappointment as expectations were raised too much by “KM hype” and focusing too much on technologies that were largely left untouched. Practitioners and researchers came to the realization that converting theory into practice was more challenging than previously thought. Some of the missing elements were ensuring that KM was not being done for KM’s sake, but that there was a clear link to organizational objectives and that all participants saw value in KM (e.g., incentives for knowledge sharing). By 2004, the field had finally shaken its burden of being yet another management fad. Organizations appreciated the holistic nature of KM and paid attention not only to tools but to organizational culture requirements for successful KM solutions.

In parallel, the nature of work evolved, with collaboration becoming the default rather than the exception, not only for our professional lives but for social interactions and learning objectives. Knowledge sharing with a group of trusted peers has become the de facto way of working, learning, and living. Knowledge management found itself in tune with these changes, which greatly facilitated its adoption as a philosophy, a mindset, a strategic perspective, and a way of interacting to create, share, and use valuable content.

Knowledge management today is being taught in top universities around the world, typically in business, computer science, education, and information studies departments. Doctoral students are completing PhD theses on KM topics. International conferences are being held around the world, with both practitioner and researcher tracks. A number of consortia and KM professional organizations have been established. The number and type of KM journals has also changed. While at first publications were primarily authored by KM tool vendors and practitioners, there has been a significant shift to more scholarly venues and publications that represent KM research rather than KM project mandates. Along with the proliferation in the number of journals, there has also been increasing specialization (e.g., *International Journal of Nuclear Knowledge Management*), more interdisciplinary journals (e.g., *Interdisciplinary Journal of Information, Knowledge and Management*), and more emphasis on international KM (e.g., *International Journal of Knowledge Management*). Up until about the year 2000, only non-peer-reviewed journals were available (e.g., *KMWorld*, *Knowledge Management Review*). Some of the major peer-reviewed KM journals available today are shown in Table 4, ordered by the first year of publication.

KM is found in all vertical industry sectors (e.g., banking, pharmaceutical), in all sizes of organizations (including volunteer-run associations with less than ten full-time employees), profit and nonprofit organizations, and organizations with a strong hierarchical structure (e.g., the U.S. military was one of the early pioneers of KM). Organizations today are defined and staffing KM positions. KM

is increasingly perceived as an element that cuts across organizational structures, projects, and silos—it enjoys a status similar to that of “quality assurance” or “ethics” and it has become a critical element of organizational viability. KM is no longer something interesting to explore—it has become subsumed in the way in which individuals, groups, and organizations work, learn, and remember.

EMERGING ROLES FOR INFORMATION PROFESSIONALS

The KM field has transformed from one led primarily by consultants and other KM practitioners to a bona fide discipline, with a distinct body of knowledge. This has been paralleled by the growing number of academic programs that offer KM as compared to the predominately private sector training that had been the only way to learn about KM up until now.^[39] TFPL^[40] is a specialist recruitment, advisory, training, and research services company

Table 4 Major peer-reviewed knowledge management journals

Journal title	Year founded
<i>IBM Systems Journal</i>	1962
<i>Journal of Managerial and Organizational Learning</i>	1970

with offices in London focusing on KM, library and information management, records management, and web and content management. Since 1987, TFPL has worked with organizations in both public and private sectors to help them develop and implement knowledge and information strategies and to recruit and train information and knowledge leaders and their teams. TFPL has drafted a KM skills and competencies guide to provide a clear and practical overview of KM skills and competencies that draws on the practical experience of organizations in a wide range of sectors and with varying approaches to KM.

In general, these KM skills include

- Time management to use their time and energy effectively for acquiring
- Knowledge (spending all day surfing the net is probably counterproductive)
- The use of different learning techniques to absorb key knowledge and learning quickly
- Effective skills of advocacy and inquiry to present knowledge to, and gather knowledge from, others
- Informal networking skills to build one's influence to gain access to people with knowledge
- Resource investigation skills
- Effective IT skills for recording and disseminating information
- Skills of cooperative problem solving
- Open dialog skills
- Flexibility and willingness to try new things and take educated risks
- Active review of learning from mistakes, risks, opportunities, and successes

The TFPL KM skills map^[41] is based on an extensive international research. The project team contacted over 500 organizations involved in implementing KM and identified the roles that they had created, and the skills that were needed in those roles, and the additional skills that were required across the organization. These key skills included an understanding of the KM concept—the philosophy and theory—and an awareness of the experience of other organizations in developing KM solutions and approaches an understanding of, and the ability to, identify the business value of KM activities to the organization, an appreciation of the range of activities, initiatives, and labels that are employed to create an environment in which knowledge is effectively created, shared, and used to increase competitive advantage and customer satisfaction.

KM roles are quite diverse and include such categories as senior and middle management roles: chief knowledge officer who ensures that KM goals are in line with organizational strategies and objectives; chief learning officer who ensures that the organization acts like a learning organization, improving over time with the help of accumulated best practices and lessons learned; and knowledge managers who are typically responsible for the acquisition

and management of internal and external knowledge. Other roles include

- Knowledge navigators, responsible for knowing where knowledge can be located, also called knowledge brokers
- Knowledge synthesizers, responsible for facilitating the recording of significant knowledge to organizational memory, also called knowledge stewards
- Content editors, responsible for codifying and structuring content, also called content managers; researchers, writers, editors—roles involving capturing and documenting knowledge
- Web developers, electronic publishers, intranet managers, and content managers
- Learning-oriented roles such as trainers, facilitators, mentors, and coaches—including those with responsibility for developing information and knowledge skills
- Human resources roles with specific responsibility for developing programs and processes that encourage knowledge-oriented cultures and behaviors
- Knowledge publishers, responsible for internal publishing functions, usually on an intranet, also called webmasters, knowledge architects, knowledge editors
- Coaches and mentors, responsible for assisting individuals throughout the business unit or practice to develop and learn KM activities and disciplines
- Help desk activities, including the delivery of KM and information related to training, also called knowledge support office

KM professionals require a multidisciplinary skillset that consists of such competencies as finding, appraising, and using knowledge, being able to reformulate questions, navigate through content, evaluate the relevance of content, filter out what is not needed, and synthesize from diverse sources in order to apply the knowledge (e.g., to make a decision). Last but not the least, they must contribute to the recording of such valuable experiences to organizational memory systems.^[42]

CONCLUSION

Knowledge management has assumed a greater priority due to the demographic pressures created by retiring baby boomers. Retirement en masse means a loss of valuable knowledge and know-how that has been accumulated by experience over the years. All organizations, regardless of type of industry, size, country, and so forth, will have to face the issue of knowledge continuity. Knowledge continuity is analogous to business continuity: while the latter targets data loss prevention due to disasters, the former targets knowledge loss due to turnover in personnel. Valuable knowledge must not only be preserved and transferred to future workers but also transferred across geographical

and temporal boundaries due to the fact that work today is spread out over networks that may extend beyond organizational boundaries. Knowledge management is the discipline and field of practice that will equip us with the necessary tools, processes, and skillset to ensure that knowledge reaches all knowledge workers so that they can carry out their work more efficiently and more effectively.

Knowledge Management Systems

Dick Stenmark

Department of Applied IT, IT University of Gothenburg, Gothenburg, Sweden

Abstract

Knowledge management systems (KMS) are loosely understood as a type of information technology (IT) to support organizational knowledge management (KM) work. The challenge here is to understand first what KM is and then figure out how it can be supported by IT. This entry first provides a review of KM work and the critique it received. Then KMS are defined and analyzed through various well-used theoretical frameworks. The major challenges KMS are facing today are discussed and the entry ends with some hints on what may lie ahead.

INTRODUCTION

Knowledge management systems (KMS) refers to a class of information systems (IS) that is used to enhance knowledge and information transfer within an organization and to manage organizational knowledge.^[1] Although this statement seems straightforward, it is rather difficult to define what a KMS is, since it is still unclear exactly what should be included in the concept of knowledge management (KM). What is the difference between knowledge and information and can computer applications really deal with knowledge? Some have argued that computers can only process data, and certainly not knowledge.^[2] What, then, is a KMS and what role does it play in KM work? Before we can talk about *systems* for KM, we need a shared view of KM itself.

Is KM an emerging new discipline of its own or is it a topic that runs across several existing scholarly discourses? Throughout the years, there have been advocates of both positions. There are also commentators arguing that organizations have always been practicing KM-related activities so there is essentially nothing new to KM. This is no uncommon phenomenon but something that happens whenever new terminology is introduced. In the 1980s, Cronin asked whether information management had something new to offer or if it was just a new label for librarianship.^[3] Twenty or so years later, people ask the same thing about KM and KMS.

Whilst several voices claim that there is no consensus regarding what exactly knowledge management is or how it differs from information management, Davenport and Grover in their editorial comment on the 2001 Special KM issue of *Journal of Management Information Systems* (JMIS) concluded that KM as a *practical* phenomenon was here to stay but that *formal research* on the topic was lacking.^[4] A couple of years have passed since Davenport and Grover made this observation and today it is fair to say that KM has established itself as a research topic, as

reported elsewhere in this encyclopedia. Davenport and Grover continued by observing that IT support for KM, i.e., KMS, was seen as a useful but far from required resource by practitioners and scholars alike.

In the following text, we shall first look briefly at the history of KM and KMS before turning to the various theories underpinning this field. Thereafter, some of the most well-cited frameworks for KMS found in the IS literature are introduced to help the reader see what *types* of KMS are available. The ontological aspects of KMS are touched upon before finally discussing the challenges KMS are facing today.

ROOTS OF KM

It can be debated when and where KM started, since it depends on what discipline you examine. A large number of fields have clearly influenced the emerging KM discourse—e.g., sociology, human resource management, organization science, and IS research to name but a few. Many commentators would probably hold organizational learning as the one discipline that has had the perhaps most profound effect on the KM field.^[5,6] When it comes to KMS, though, the IS discipline has taken a leading role, since the development, implementation, and use of systems to informate and automate are central to the IS field.^[7]

Tiwana^[8] places the roots of KM in the 1950s management literature, whereas Maier^[6] traces the first instances of KM back to the studies of societal application of knowledge in the late 1960s and early 1970s. However, it was not until the late 1980s, through the writings of, e.g., Sveiby and Lloyd^[9] and Wiig,^[10] that the phenomenon started to receive more widespread attention. Nonaka and Takeuchi's book "The Knowledge Creating Company"^[11] is also an early landmark in organizational KM

literature and one of the most cited sources with almost 10,000 references in Google Scholar.

What propelled the development of KM as a new research discipline was the growing emphasis on knowledge work and knowledge workers as the primary source of productivity as opposed to assets such as land or capital.^[11] This view paved way for the knowledge-based perspective of the firm^[12] that suggests that the tangible resources of an organization generate value dependent on how they are combined and applied, which in turn depends on the organization's knowledge. This knowledge is deeply permeated in culture, procedures, routines, systems, and minds of the individual employees.

In the introduction of their 2001 paper, Alavi and Leidner note that it is not the existence of this knowledge per se that matters, but the ability to apply it and put it to use. To that end, advanced information technologies can be instrumental in effectuating the knowledge-based view of the firm by systemizing, enhancing, and expediting large-scale knowledge management.^[13]

CRITIQUE OF KM

Knowledge management as a research discipline has also received critique. Some have argued that it is no more than yet another exemplar in a long list of management fads that have come and gone over the years.^[2,14] In his critical analysis of KM, Wilson concludes:

[Knowledge management] is, in large part, a management fad, promulgated mainly by certain consultancy companies, and the probability is that it will fade away like previous fads.^[14]

Much of this skepticism stems from the fact that many consultancy firms and software vendors simply seemed to have renamed their old services and products, replacing the term "information" with the term "knowledge." Therefore, says Wilson:

[T]he confusion of 'knowledge' as a synonym for 'information' is one of the most common effects of the 'knowledge management' fad.^[14]

In addition to the fad debate, the KM discourse was also criticized for being "technology-driven." Comparing and contrasting the KM literature to that of organizational learning (OL), Swan et al. found that although the two disciplines are concerned with the improvement of organizational performance through knowledge development, i.e., human issues, only the OL literature focused on humans whereas the KM literature was predominantly occupied with tools and techniques.^[5] The emphasis on information technology in the KM literature resulted in people being marginalized to either "inputs to KM [...]"

or as constraints on its effectiveness [...]" (p. 673).^[5] Swan and colleagues argue that much of the richness of human relations is lost when KM is reduced to merely technology.

This distinction between technology-oriented and human-oriented approaches has a long tradition in organization science and goes back to at least the early 1980s. However, a more holistic understanding of KM that encompasses both these stances has developed, and much of the turf wars from the late 1990s have now abated.

THEORETICAL FOUNDATION

Much of the epistemology used in KM literature has been influenced by the separation of knowledge in a tacit and an explicit component. The notion of tacit knowing is attributed to philosopher Michael Polanyi but was introduced to the KM discourse by Nonaka and Takeuchi.^[11] Interestingly, the commonly used tacit-explicit distinction is not directly derived from Polanyi's work. Most commentators see explicit knowledge as knowledge that has been captured and codified into manuals, procedures, and rules, and is easy to disseminate. Tacit knowledge, on the other hand, is then knowledge that cannot be easily articulated and thus only exists in people's hands and minds, and manifests itself through their actions. In contrast, Polanyi does not make such a distinction. Instead, he envisions tacit knowing as the backdrop against which all understanding is distinguished.

While Polanyi speaks of tacit *knowing*, i.e., the verb, as a backdrop against which all actions are understood, Nonaka and Takeuchi use the term tacit *knowledge*, i.e., the noun, to denote particular type of knowledge that is difficult to express. This view has been criticized but due to the strong influence of Nonaka and Takeuchi's writings on the knowledge management discourse, this interpretation has been widely adopted. Amongst the critics are Tsoukas, who argues that tacit knowledge is *not* explicit knowledge internalized. Instead, tacit knowledge is inseparable from explicit knowledge since "[t]acit knowledge is the necessary component of all knowledge" (p. 14).^[15] According to Tsoukas the two are so inseparately related that to even try to separate the two would be to "miss the point." There had perhaps been less confusion had Nonaka instead used the term "implicit knowledge."

Tsoukas recognizes that the dichotomy between tacit and explicit knowledge and the taxonomies derived from this duality have advanced our understanding of organizational knowledge by showing its multifaceted nature. However, such typologies also limit our understanding by the inherent formalism that accompanies them. "The conceptual categories along which the phenomena are classified must be assumed to be discrete, separate, and stable. The problem is that they hardly ever are" (p. 14).^[15]

The tacit–explicit dichotomy has also taken other expressions. Choo suggests a differentiation between tacit, explicit, and cultural knowledge,^[16] and Spender suggests, in addition to tacit and explicit knowledge, individual and collective knowing.^[12] Blackler speaks of embodied, embedded, embrained, encultured, and encoded knowledge.^[17] Yet another derivative is the distinction between the community view and the commodity view. The community view sees knowledge as socially constructed and inseparable from the knower, whereas the commodity view holds knowledge as a universal truth, and as facts and collectable objects.^[18] Though several other ways to classify knowledge exist and have been suggested, they all, more or less, build on the tacit–explicit dichotomy.

DEFINITION OF KM SYSTEMS

Whereas most people agree that data and information may exist outside humans, supporters of the community view of knowledge have argued that knowledge can never be separated from the knower and thus never stored digitally.^[2,13] Computer support for knowledge management would thus be, in a sense, impossible. How can we then talk about KMS?

KMS is often employed as a catalyst or enabler of KM but such implementations should not be carried out without careful coordination with the required people-oriented activities needed. Alavi and Leidner note that while KM initiatives may not *require* tools, IT can certainly support KM in many ways, in particular in firms where the ratio of *knowledge workers* is high.^[13] Schultze defines a knowledge worker as someone who interacts knowledgeable with information and sees information not only as something derived from knowledge but as something that changes knowledge.^[19] There is thus a tight relationship between information and knowledge and it seems that any knowledge work needs to be supported by information technology.

As stated in the introduction, a KMS is an IS and IS and knowledge systems are thus not radically different; instead, there is a subtle yet important difference in the *attitude* towards and the *purpose* of the systems. Whereas an IS processes information without engaging the users, a KMS must be geared towards helping the users to understand and assign *meaning* to the information.^[13] The value of any given piece of information resides in the relationship between the information and the user's knowledge. This means that design of KMS should be based on an understanding not only of the information per se, but also of the context where the user develops the information need, and the analysis of the usage of the same information once it has been obtained and interpreted by the user.^[20]

Following Alavi and Leidner,^[13] a KMS should thus be understood as *a particular class of information systems*

developed specifically to support organisations in their attempt to create, codify, collect, store, integrate, share, and apply knowledge.

KMS THEORY

The theoretical foundation underpinning KMS vary considerably and are not easily detected but we can get a reasonably good picture by looking at Schultze and Leidner's classification of theoretical perspectives in KM-related IS research. Having reviewed six leading IS journals and thoroughly analyzed nearly 100 articles from 1990 to 2000, Schultze and Leidner showed that a vast majority or 70% belonged to the Normative Discourse, 25% could be labeled as Interpretative Discourse and only a handful of papers represented a Critical (or Dialogic) Discourse.^[21]

According to Schultze and Leidner's analysis, the normative discourse, which is characterized by a strive towards consensus from an a priori understanding of what the research problems are, typically assumes progressive enlightenment and increasing rationalisation, management, and control. IS research representing the normative discourse are thus concerned with "codification, normalisation of experience and the search for law-like relationships" (pp. 216–217).^[21] Much of the research focus on problem solving, and it creates "a problem space that can be decomposed in a logical, top-down fashion" (p. 221).^[21] Although both the research topics and the way knowledge is operationalised show great diversity, a common metaphor used within the normative discourse is that of knowledge as an asset. Researchers in this category typically view knowledge as a key driver of organizational efficiency and performance. Amongst the theories underpinning normative research, Schultze and Leidner mention innovation diffusion theory, absorptive capacity theory, and management cognition theory (p. 222).^[21]

The interpretative discourse, which also opts for consensus but from an emergent understanding of the organizational situation, emphasizes the social aspects of organizational life that has not been rationalized or systematized. IS research representing the interpretative discourse thus aims "to create a coherent, consensual, and unified representation of what the organisational reality is 'actually' like" (p. 217).^[21] and is typically targeted on work situations and organizational practices. Knowledge is therefore studied indirectly via its role in organizational transformation and how it is supported by various types of KMS. In this discourse, knowledge, technology, and organisational practice are all seen as socially constructed and dynamic, and the theories upon which interpretative research rests include organisational learning, communities of practice, activity theory, and bricolage (pp. 224–225).^[21]

It is evident that almost all KM-related IS research is consensus-oriented. There are, however, also those who apply a dissensus-oriented approach. Although Schultze and Leidner treat critical and dialogic as two separate discourses, I shall here use the critical discourse label to include both these perspectives, since both understand struggle, conflict, and tension as natural organizational states. Seen from this perspective, organizations are “sites of political struggle and fields of continuous conflict” (p. 217)^[21] and the objective of the research is thus to show that there is no coherent reality but different forms of domination and distortions. KMS (and other IT tools) are thus not to be understood as neutral, according to this perspective, but should be seen as instruments to make invisible work visible or to actively change social conditions. Schultze and Leidner call for more research in the critical discourse since this perspective allows the highlighting of the social inequities underpinning the distinction between service and knowledge work and the examination of contradictions in managing knowledge.^[21] The direct implications for KMS, however, are less obvious.

TYPES OF KMS AND ITS APPLICATIONS

As we saw earlier, many vendors tried to repackage their applications under the KM label at the end of the last millennium and a list of different KMS can therefore be made arbitrarily long. Instead of presenting a list of software that not all would agree upon, and, in addition, soon would be dated, it is more useful to examine three of the most referenced classification schemes for KMS and let them define the *various types of applications* that are possible. The frameworks are Hansen et al.’s *Codification vs. Personalization* from *Harvard Business Review* in 1999,^[22] Hahn and Subramani’s *Knowledge Residence and Level of Structure* from ICIS 2000,^[23] and finally Alavi and Leidner’s scheme from MISQ in 2001.^[13]

Codification vs. Personalization

An early framework for KM work (and hence for KMS to support that work) is found in Hansen et al.’s well-referred article from *Harvard Business Review*. Based on their studies of management consultancy firms, and implicitly building on Nonaka’s dichotomy of explicit and tacit knowledge, Hansen et al. divide knowledge management efforts into two different strategies; codification and personalization.^[22]

Companies where the KM strategy centers on codifying and storing knowledge into databases for easy dissemination and retrieval is said to follow a codification strategy. In such companies, computers have a central role in the strategy, as carriers of knowledge. Hansen et al. point to Ernst and Young as a company following

a codification strategy. Knowledge is harvested and coded into documents or other “knowledge objects” as an informant called them (p. 108),^[22] and these are thereafter stored in electronic repositories for later retrieval. Even though the codification process is laborious, Ernst and Young has dedicated staff members doing nothing else but codifying knowledge into documents—this approach allows for scaling up since the repositories are accessible for all employees worldwide and available around the clock. Once the object is put into the repository it can be used over and over again at a very low cost, provided it does not have to be modified. Companies using the codification strategy thus typically deal with problems where the same solution can be applied many times. The “economics of reuse” is what motivates the KM efforts in these companies, and the KMS used are typically document management systems and databases.^[22]

In contrast, when knowledge is tied to the individual that developed it and thus cannot be stored in a database, it has to be shared through face-to-face interactions. The role of the computers is thus to facilitate communication between people. Companies with this approach are said to follow a personalization strategy, and Hansen et al. mention McKinsey as a company in this category. In their company, knowledge emerges out of dialogues between individuals and their IT focus is thus to enable interactions between employees. Part of McKinsey’s KM strategy is to move people between offices to expand their networks. Even though face-to-face meetings are unequalled for sharing tacit knowledge, space and time distances may sometime prevent people from physical meetings. McKinsey thus engage e-mail and video conferencing equipment to communicate and allow employees tap into the expertise of their peers. Companies following a personalization strategy typically deal with unique problems that do not have clear solutions and where customized answers must be provided. In “experts economics” knowledge is tacit and cannot be systematized and made efficient. Instead, these companies charge much higher prices, and KMS used are expert finder systems and communications software.^[22]

Hansen et al. stress that companies should not try to combine these two strategies but, based on their business strategy, select one as their main KM strategy and merely use the other as a complementary strategy.

Knowledge Residence and Level of Structure

Adding another dimension to the tacit–explicit dichotomy, Hahn and Subramani present a framework for KMS by looking on the one hand at where the knowledge is said to reside (i.e., in artifacts or in people) and on the other hand to the extent to which knowledge is said to impose or

require an a priori structure. These axes form a two-by-two matrix hosting four different classes of KMS.^[23]

- One is where the system manages knowledge artifacts that has an inherent structure or where the system imposes a structure on the artifacts. Formal document repositories and data warehouses belong to this class.
- A second class also requires an a priori structure but manages links to knowledgeable people. A competence database intended to let employees find colleagues with specific skills falls into this class.
- A third class does not impose any structure in particular and assumes that knowledge is codified into artifacts. Intranets where Web pages and documents are found through full-text indexing search engines belong to this class.
- Finally, a fourth class again requires no structure but provides means for employees to identify and communicate with local experts. Discussion forums and e-mail Listservs are systems in this class.

Hahn and Subramani identify three interesting challenges regarding KMS. First, balancing information overload and potential useful content involves the size and diversity of both the users and the content. When the knowledge resides in artifacts, more items means higher chances of being able to find what you need. Also when human resources are required, more users increase the possibilities of finding a knowledgeable coworker. The down side is that more information also means more unrelated or useless information, and more users typically generate more interactions and more e-mails, which blurs the picture. For the same reason is diversity useful, and no problem in highly structured environments, but when structures and shared vocabularies are lacking, diversity can easily get overwhelming.^[23]

Second, balancing additional workload and accurate content addresses the issue of keeping KMS updated. Highly structured environments require considerable efforts to ensure the appropriateness of the structure, and this work often comes on top of the employees' ordinary work tasks. In more loosely structured systems motivation to share knowledge often comes in the form of higher social status. The downside is that those who contribute and earn a reputation may end up being occupied answering people's questions and helping colleagues instead of doing their jobs.^[23]

Third, balancing exploitation and exploration means being aware of the fact that reliance on existing solutions only may result in a competency trap.^[24] A system that supports the exploitation of existing knowledge may provide short-term benefits but in the long run be detrimental to the organization. At the same time, a system preoccupied with generating new knowledge may prevent organizational members from learning and adding to the collective experience that exists in the organization.

Hahn and Subramani suggest the KMS should consider including agent technology, collaborative filtering methods, advanced visualization tools, in order to address the above challenges.^[23]

Alavi and Leidner's Scheme

Without suggesting an explicit framework, Alavi and Leidner in their review of the literature discussing applications of IT to knowledge management efforts, identify three common approaches: Coding and sharing of best practice, Creation of knowledge directories, and Creation of knowledge networks [¹³, p. 114].

Coding and sharing of best practice is one of the most common applications of KMS, according to Alavi and Leidner. The term "best practice" is typically used to refer to a superior or exemplary practice that leads to superior performance. By collecting and codifying stories that mediate such practice, organizations can build KMS that stores and disseminates these experiences within the organization.

Creation of knowledge directories forms a second common class of KMS. Knowledge directories are also known as expert finder systems and aim at mapping the internal expertise of the organization. Alavi and Leidner report that 74% of the respondents in Gazeau's survey believed that their organization's most useful knowledge was not available in explicit form. When knowledge cannot be codified into artifacts, creating knowledge directories allows organizational members to benefit from the knowledge by being able to find and subsequently talk to the knowledgeable coworker.

Creation of knowledge networks is the third commonly used approach to KMS. Applications to first identify and then bring together (virtually or face-to-face) people from the same community of practice or those who share an interest has proven useful in many organizations. Ford Motor Company found that by sharing knowledge in networks the development time for cars was reduced by 33%. Online forums belong to the technology used in this approach.^[13]

We have seen that KMS can either be used to support a commodity view of KM, where the explication of knowledge is assumed not only to be possible but also necessary, or a community view of KM, where the implicit nature of knowing puts people in focus. The success of KMS (as with most IS) depends on the extent of use, which in turn depends on a number of factors. In their concluding discussion, Alavi and Leidner point to a set of research questions concerning the application of IT to KM. In sum, they ask what effect an increased breadth and depth of knowledge via KMS would have on organizational performance; how to ensure that knowledge in an KMS can be modified (if necessary) prior to being used, and how these modifications too can be captured; how anonymized knowledge in a KMS can be trusted; and what are the quality and

usefulness factors of KMS.^[13] The answers to many of these questions are still pending.

ONTOLOGICAL ASPECTS

It has often been argued that only individuals can think and act—not organizations. At the same time, as human beings we are social creatures and we tend to seek, and benefit from, each other's company. Inputs from colleagues and the surrounding context greatly affect our ability to create and use knowledge because the individual and the collective interact in fruitful ways. Focusing primarily on how new knowledge emerges, Nonaka and Takeuchi stress the fact that knowledge creation initiates from the individual but is a process that moves through expanding communities of interaction, crossing group, division, and, finally, organizational boundaries.^[11] Other scholars have made similar comments about other KM processes.

Still, IT support for KM has traditionally focused on organizational-wide systems, possibly due to the acknowledged fact that the usefulness of a KMS grows exponentially with the size of the organization. Much of the IS research has thus had a macro-level focus, but also applications supporting organizational learning and organizational memory are common in the KMS repertoire. The challenge associated with organizational KMS is that individuals often have to provide input without getting much back in return. This problem, often referred to as the maintenance problem seriously threatens the quality and usefulness of these systems.

Another category of KMS are the groupware systems targeting smaller subsets of the organization, typically aiming for management. This category includes various types of Decision Support Systems (DSS). Many KMS in this category can also be related to the field of Computer-Supported Collaborative Work (CSCW). Typical applications here include Helpdesk applications and expert finder systems within specific subgroups. The maintenance problem continues to be a challenge also at this level.

When it comes to the individual, there has—until recently—not been equally much support. Some argue that this situation is about to change. One of the problems here is that not all of the applications used at an individual level are officially labeled KMS. For example, the information retrieval (IR) field has provided the knowledge worker with search engines and other tools to help locate information, but not all would agree that a search engine is a KMS. Another noticeable trend is the growth of social media. These applications exploit the individual-collective relationship and are able to provide the individual with added value through the actions of the collective relationship and vice versa. It will be interesting to follow this development to see whether social media will provide a means to avoid, if not solve, the maintenance problem.

THE KMS CHALLENGES

A number of KMS challenges can be identified in the KM literature. One issue is that of dispersion of work. It is argued that knowledge workers are increasingly dispersed—spatial as well as contractual.^[25] Organizational members work outside the physical boundaries of the firm and/or change positions within the firm, often including geographical changes. This, it is argued, makes them less exposed to colleagues with similar functional skills.

There is also the contractual dispersion, i.e., the provisional nature of employment and the higher level of partial or temporary involvement in the firm that many knowledge workers experience. In addition, many are engaged in virtual teams that often reorganize and have high turnover rates. This dispersion of work requires KMS that allows for effective sharing of the latest knowledge.^[25,26]

Another issue is the shorter product and process life cycles in today's organizations.^[26] This compresses the time window for capturing the lessons learned and knowledge created in the process and leaves the knowledge workers with little time to document and save their experiences. At the same time knowledge becomes obsolete much quicker. KMS need to be able to deal effectively with these circumstances.

The above concerns can be seen as aspects of a larger and overarching challenge, i.e., how to keep KMS updated and current. While many of today's organizations expect KMS to become major catalysts for innovations in terms of the ways in which businesses can be organized and conducted, there is plenty of IS research that indicate that such systems often fail when implemented in everyday knowledge work. In response, a distinguishable issue in KMS research is how to support knowledge work with IS in a successful way. It has been found that although the systems work technically and should function well in theory, they remain unused by the organizational members.^[27] Following this, the development of systems with the capacity to bridge the knowing-doing gap in organizations has been recognized as a significant area of KMS research.

However, the imbalance between the desire for accurate content and the workload required to achieve this still appears to be a critical problem, leading to systems of little use for organizations in their knowledge application processes. It has been suggested that the problem stems from the fact that the requirements for KMS are fundamentally different from those of other types of IT and are thus not covered by existing IS design theories.

Markus et al. have identified three primary differences.^[28] First, knowledge work processes requires that expert knowledge is adapted and/or contextualized to specific local conditions. Decision support systems and executive IS do not provide system features that can handle

expert knowledge or contextualize translation rules. Resulting from this, DSS and expert systems inhibit creative problem finding and solution generation. While expert systems manage general expert knowledge, they fail to support contextual knowledge and the flexibility needed for process emergence. Second, these types of systems are all specifically designed for a known type of user, e.g., managers. Being designed for a particular type of user community, these systems are not well adapted to emergent work processes characterized by shifting user types having varying knowledge requirements. Third, knowledge workers have access to many different types of systems but since these systems often are isolated and not integrated into work practice, knowledge workers tend to manage their systems rather than getting the job done.

To circumvent these problems, it has been suggested that KMS should be integrated with or build into already existing applications since key to a successful KMS is to facilitate usage.^[29] As knowledge work requires creativity in order to produce idiosyncratic and esoteric knowledge, knowledge work practice is untidy compared to operational or administrative business processes. Hence, KMS must be able to go beyond written instructions and official task descriptions, thus appreciating exceptions not only as something inevitable but as a necessity. Consequently, KMS must not be isolated but should be integrated into work practice. For the purpose of avoiding situations where knowledge workers manage their systems rather than getting the job done, developers must recognize sociotechnical issues associated with disparity in work and benefit. In this way, KMS capable of attracting a critical mass of users can be developed. In addition, paying attention to unobtrusive accessibility and the adoption process may deepen developers' understanding of how support systems can be better integrated with both the day-to-day tasks of knowledge workers and their performance of the tasks.

CONCLUDING SUMMARY

In the 1990s there was a rather heated debate whether or not KM was a fad but this seems to have abated. Now, there is consensus that KM—at least as a pragmatic issue—is here to stay. With knowledge replacing economy of scale as business driver and with increasing portion of knowledge workers in today's organizations, knowledge management, and the need for IT support for it, is not likely to go away.

The strong focus on technology that we witnessed in early KM work has been compensated for and practitioners and researchers alike now have acknowledged that knowledge cannot exist outside the mind of a human being. Cultures that encourage and motivate individuals to share, combine, and reuse knowledge are recognized as equal, if not more, important as IT, even amongst technologists. IT

is still likely to continue to play an important part, not as driver and single success factor but as catalyst, facilitator and enabler of social networks, virtual meeting places, and new discussion forums. One of the general lessons learned is that technology is important and useful but it should not be the driving force in KM work.

Several commentators have pointed to the fact that KMS in the late 1990s were discrete, stand-alone systems not aligned with the organizations' business processes. Such systems had to be explicitly attended to on top of ordinary tasks, thus adding to—not facilitating—the work to be carried out.^[29] Newer KMS appear to be better integrated with existing business infrastructure and enterprise applications, thereby allowing employees to seamlessly apply organizational knowledge in whatever work they are engaged. However, there is still a need for development and research in this area.

On the theoretical side, no core theory on knowledge management has yet been developed, and KM may still be understood as an “umbrella construct,” i.e., a broad and somewhat unclear label that is used to contain a whole variety of loosely connected issues.^[30] Without a clear theoretical focus, some commentators argue, the original concept risks being eroded until it has no value and collapses, as researchers explore divergent paths and build isolated islands of knowledge. Spender^[31] has argued strongly that KM and KMS research need a core theory that distinguishes them from other fields but at the same time is narrow enough to allow laypeople to recognize and understand what is and what is not a KMS. Not much work is currently to be found along such lines.

In their editorial introduction to the 2003 special issue on KM and IT in *IT and People*, Gray and Meister argue that KMS researchers are facing a bigger problem than did researchers of earlier organizational phenomena, since knowledge is neither new nor physically present and there is thus nothing concrete to point to. An independent core theory of KM and KMS is therefore needed, they argue.^[32]

However, several future scenarios are possible. If the development towards more knowledge work continues, we may end up in the scenario predicted by Davenport and Grover where “every industry will view itself as knowledge-intensive [^[4], p. 4]. If everything is KM, will the concept then still be meaningful, and if every application is a KMS, will the term be useful? At the other end of the spectrum lies a scenario where KM becomes so diversified and scattered that for this reason is pointless to talk about KM and IT support for it. Where we will end up remains to be seen.

Abstract

Knowledge management (KM) as a business concept, though it had earlier antecedents, evolved in the late 1980s. It sprang from the combination of the recognition of the importance to a firm of its information and knowledge assets, and from the appearance of the Internet and the recognition of the utility of the Internet as an information and knowledge sharing tool, particularly for geographically dispersed organizations. KM has gone through four stages:

1. An emphasis upon the new technology, the Internet, and upon the development of “best practices” or “lessons learned.”
2. An increased recognition of human and cultural factors, and upon the development of “communities of practice” to facilitate the sharing of information.
3. An increased recognition of the importance of designing the systems for retrievability, and the importance of data design and taxonomies.
4. An emphasis upon extending KM systems beyond the parent organization to include, for example, vendors and suppliers, customers, users, alumni, etc.

KM has exhibited remarkable staying power and growth in a fashion that is dramatically different from other business enthusiasms of the late twentieth century.

INTRODUCTION

This entry is a discussion of the historical origin of the phrase/concept called “Knowledge management (KM).” While KM is a recent development of information and communication technology (ICT) becoming integrated with business practice and intellectual capital (IC), it should not be ignored that the capture and passing on of “knowledge” is an ancient practice. In that sense, KM could be traced at least as far back as the thirteenth century and the Dominican Order’s development, manufacture, and promotion of concordances for organizing and accessing knowledge within the Bible.

The use of the term “knowledge management” is a surprisingly recent phenomenon, becoming common and part of the professional vocabulary only in the mid-1990s. The earliest print reference appears to have been used first in the context of library and information work. Marchand,^[1] then Dean of the School of Information Studies at Syracuse University, coined it in the 1980s as a descriptor for the final level in his stage hypothesis of information systems development.^[2] However, the term, as presently used, appears to have been re-coined more or less anonymously somewhere among the major accountancy and consulting firms. The earliest reports seem to be from McKinsey & Co. Brook Manville, the first Director of Knowledge Management at McKinsey, reports that
